13. ABSTRACT <i>(Maximum 200 words)</i>  Previous work from our laboratory has shown that c-Src and the EGFR interact synergistically in a fibroblast model system to potentiate mitogenesis and tumorigenesis, providing a model system for the study of human breast cancer. We have identified a c-Src-dependent phosphorylation of the EGFR, Tyr 845, which is required for EGF and serum induced mitogenesis. Here, I show that G-protein coupled and cytokine receptor coupled signalling pathways are able to induce phosphorylation of the EGFR on Tyr 845, and that c-Src kinase activity is required for this phosphorylation to occur. Moreover, expression of a Y845F form of the EGFR in fibroblasts decreases DNA synthesis in response to at least two GPCR agonists: endothelin and LPA. Crosstalk also appears to exist between the EGFR signalling pathway and that regulated by the steroid hormone estrogen, in that estrogen dependent DNA synthesis in MCF7 cells can be reduced to nonstimulated levels by the introduction of a Y845F mutant form of the EGFR. Taken together, these data suggest that phosphorylation of EGFR Tyr 845 is a central, critical event that is common to a variety of mitogenic signalling pathways.

## INTRODUCTION

The research I have undertaken during the past year has been directed at elucidating the biochemical mechanisms that regulate cross-talk between the EGFR and other signalling pathways. Recent work in our laboratory has established the importance of a c-Src-dependent phosphorylation site on the EGFR, namely, Tyr 845. Mutagenesis studies have demonstrated that phosphorylation of this site , which is present in the catalytic portion of the EGFR molecule, plays a crucial role in EGF- and serum- induced mitogenesis. The finding that serum-induced DNA synthesis was affected by a Y845F mutant form of the EGFR, along with recent work from other laboratories which showed that the EGFR becomes tyrosine phosphorylated and activated in response to a variety of G protein coupled receptor agonists and cytokines, suggests that the phosphorylation of the EGFR may be a common signalling event shared by several pathways within the cell. My work has focussed on investigating the interaction between pathways regulated by G protein coupled receptors, cytokines, and estrogen, and the c-Src dependent phosphorylation of EGFR Tyr 845. I have used phosphotryptic mapping techniques to investigate the phosphorylation state of Tyr 845 in response to activation of the above signalling pathways, as well as measurement of bromodeoxyuridine incorporation to see if Tyr 845 phosphorylation is necessary for mitogenesis downstream of these pathways.

## ANNUAL SUMMARY

Increased expression or activity of tyrosine kinases, and the subsequent deregulation of downstream signalling cascades, is thought to play a major role in the genesis and progression of many different human cancers. The nonreceptor tyrosine kinase c-Src, and the epidermal growth factor receptor (EGFR), are especially implicated in breast cancer (reviewed in Biscardi et al., 1999). Overexpression of the human EGFR (HER1) and/or the related family member HER2 occurs in 20-30 % of human breast tumors and, in the case of HER1, correlates with the loss of estrogen responsiveness (Sainsbury et al., 1985; Singletary et al., 1987; Koenders et al., 1991; Slamon et al., 1986). Further work suggests that HER1 may be involved in later, more aggressive stages of breast cancer (Sainsbury et al., 1987; Toi et al., 1991; Battaglia et al., 1988). c-Src also plays an important, but as yet undefined, role in human breast cancer. Ottenhalf-Kalff et al. (1992) showed that 100% of primary human breast tumors examined displayed increased tyrosine kinase activity, and 70% of this cytosolic activity could be attributed to c-Src.

The dual overexpression of both the EGFR and c-Src in many of the same human tumor types suggests that they may interact in some manner to control cellular events which could lead to transformation and tumorigenesis. Indeed, our laboratory has used fibroblast model systems, human breast cancer cell lines, and tumor tissues to demonstrate that overexpression of both these kinases results in increased tumorigenesis in nude mice, as well as enhanced signal transduction emanating downstream of the receptor (Maa et al., 1995; Biscardi et al., 1998). The EGFR and c-Src physically associate in cells where they are co-overexpressed, such as our fibroblast model system (5HR11; Maa et al., 1995) and several breast cancer cell lines (MDA 468, MDA 231, BT-20, BT-549, and SKBR3; Biscardi et al., 1998). Interestingly, the EGFR becomes phosphorylated on two novel tyrosyl residues when in association with c-Src, namely Tyr 845 and Tyr 1101 (Maa et al., 1995; Biscardi et al., 1999). Tyr 845 lies in the catalytic domain, in a highly conserved, critical region of the tyrosine kinase activation loop. Mutation of the analogous residue in numerous other tyrosine kinases results in ablation of tyrosine kinase activity (Ellis et al., 1986; Fantl et al., 1989; van der Geer and Hunter, 1991; Vigna et al., 1994; Mohammadi et al., 1996; Zhang et al., 1998). However, other groups have not been able to convincingly demonstrate the phosphorylation of Tyr 845.

Tyr 845 has been the focus of recent publications from our laboratory. Tyr 845 phosphorylation was observed in c-Src associated EGFR from EGF-stimulated MDA 468 breast cancer cells, and this phosphorylation could be increased further by overexpression of c-Src in these cells (Biscardi et al., 1999). Moreover, 10T1/2 fibroblasts expressing a Y845F mutant form of the EGFR were impaired in their ability to synthesize DNA in response to both EGF and serum, which suggests that phosphorylation at this position is important for mitogenic signalling downstream of EGF and other agonists (Biscardi et al., 1999; Tice et al., 1999). Tyr 845 phosphorylation is observable only in cells where both c-Src and the EGFR are overexpressed and are physically associated, a situation that is often found in breast cancer cells and that roughly correlates with increased tumorigenicity (Biscardi et al., 1998). This finding provides compelling evidence for studying the contribution that EGFR Tyr 845 phosphorylation may play in tumorigenesis.

10T1/2 fibroblasts which coexpress wild type EGFR and kinase inactive c-Src (430R cells) are impaired in their ability to grow in soft agar and to form tumors in nude mice, when compared to their counterparts which overexpress wild type forms of both kinases (5HR cells; Tice et al., 1999). While the EGFR is still capable of associating with c-Src in response to EGF treatment of the 430R cells, the receptor is not phosphorylated on Tyr 845 (Tice et al., 1999). These results indicate that the c-Src dependent phosphorylation of EGFR Tyr 845 is a necessary event for EGF-induced mitogenesis and tumorigenesis.

Recent work from several laboratories (Dikic et al., 1996; Daub et al., 1996, 1997; Luttrell et al., 1997; Cunnick et al., 1998; Yamauchi et al., 1997) has shown that phosphorylation of the EGFR can be elicited by a variety of different agonists, including those that bind G-protein coupled receptors (GPCR) and cytokine receptors. The finding that serum-induced growth is also dependent on phosphorylation of EGFR Tyr 845 suggests that this phosphorylation is involved in mediating signalling via G protein coupled receptors. Lysophosphatidic acid (LPA), which is the active ingredient in serum, binds a Gi/Gq linked receptor and previously has been shown to induce phosphorylation of the EGFR and activation of signalling molecules downstream of the EGFR in COS cells (Daub et al., 1997; Luttrell et al., 1997). Studies using kinase inactive c-Src, pharmacological inhibitors of c-Src, or expression of CSK (Cellular Src Kinase), which inactivates c-Src, have shown that c-Src kinase activity is required for the LPA-dependent phosphorylation of the EGFR (Daub et al., 1997; Luttrell et al., 1997). Thrombin (THR), and endothelin (ET) other GPCR agonists, also induce the phosphorylation of the EGFR in when the required G protein is expressed in COS cells (Daub et al., 1996, 1997). Additionally, EGFR phosphorylation is triggered by growth hormone (GH), a cytokine receptor coupled agonist, in mouse liver (Yamauchi et al., 1997). The fact that EGFR becomes phosphorylated in response to a variety of different extracellular stimuli suggests that this receptor tyrosine kinase may be a central regulator of signalling events in the cells. My current work has focussed on elucidating the contribution of EGFR Tyr 845 to signalling downstream of these G protein- and cytokine- receptor coupled agonists.

To determine whether Tyr 845 became phosphorylated as a result of activation of G protein or cytokine receptor coupled pathways, 10T1/2 fibroblasts expressing either wild type EGFR and wild type c-Src (5HR cells) or wild type EGFR and kinase inactive c-Src (430R cells) were stimulated for 10 minutes with EGF, ET, GH, isoproterenol (ISO), LPA, or thrombin (THR). Cells were lysed in RIPA buffer and subjected to an EGFR immunoprecipitation followed by a phosphotyrosine immunoblot (Fig. 1, Appendix). While EGF caused the greatest degree of EGFR tyrosine phosphorylation, significant increases in EGFR phosphorylation were also elicited by ET, GH, LPA and THR. ET and GH elicited the more robust responses, while isoproterenol induced little to increase in EGFR phosphorylation, suggesting that the G<sub>s</sub> $\alpha$  coupled pathway and the EGFR pathway do not interact. These agonists were able to induce tyrosyl phosphorylation of the EGFR in both 5HR and 430R cell lines. However, the level of phosphorylation was lower in the 430R cells, indicating that c-Src is necessary for these phosphorylations to occur, as has been previously shown in the case of LPA (Daub et al., 1997; Luttrell et al., 1997). These results demonstrate that the EGFR becomes phosphorylated in COS cells in response to a variety of extracellular stimuli, and because of this, the EGFR may participate in a large array of signalling pathways within the cell.

To determine if the EGFR and c-Src were able to physically associate in response to these agonists, c-Src immunoprecipitates from CHAPS lysates of 5HR cells treated for 10 minutes with the above agonists were subjected to an immune complex kinase reaction (Fig. 2). Lefkowitz and colleagues (1997) have previously shown that LPA is capable of triggering the formation of a c-Src/EGFR heterocomplex in COS cells. As our laboratory has previously shown (Maa et al., 1995; Biscardi et al., 1999), EGF treatment of fibroblasts or breast cancer cells which overexpress both c-Src and EGFR causes the physical association of c-Src and the EGFR. Interestingly, treatment of 5HR cells with ET, GH, LPA and THR also induced association between c-Src and EGFR. LPA treatment resulted in a very robust association, while ET, GH, and THR triggered association to a lesser extent. Treatment with these agonists did not appear to affect the autophosphorylation of c-Src. However, it remains unclear whether the GPCR and cytokine-receptor coupled agonists act to increase EGFR phosphorylation by increasing the EGFR's ability to autophosphorylate, or by increasing the ability of c-Src to phosphorylate the receptor. While c-Src kinase activity does not appear to be altered by treatment with these agonists, it is possible that treatment with GH, LPA, ET and THR results in the movement of c-Src to a particular subcellular signalling complex, where it is in a more optimal position to phosphorylate the EGFR.

To gain further insight into the GPCR-and cytokine coupled receptor mediated phosphorylation of the EGFR, tryptic phosphopeptide mapping was performed on the c-Src associated EGFR derived from 5HR and 430R cells treated with the panel of agonists. GH, LPA and ET all triggered the phosphorylation of Tyr 845 (previously identified in response to EGF (Maa et al., 1995; Biscardi et al., 1999)) in the c-Src associated EGFR derived from 5HR cells (Fig. 3, bottom row). Interestingly, no phosphorylation of Tyr 845 was observed in response to any of the treatments in 430R cells (Fig. 3, top row), indicating that the phosphorylation of Tyr 845 requires c-Src kinase activity. The other c-Src dependent phosphorylation, Tyr 1101, was also present in these cells, but agonist treatment did not increase its phosphorylation over unstimulated levels (data not shown). Additionally, the tryptic map derived from c-Src associated EGFR from ISO treated 5HR cells showed a barely visible pattern of spots, with no Tyr 845 phosphorylation observed (data not shown). Thus, unlike the Gq (ET) and Gi/Gq (LPA) coupled pathways, the G $\alpha$  coupled pathway is unlikely to interact with EGF-mediated signalling. These results suggest that the phosphorylation of EGFR Tyr 845 is a more general phenomenon which occurs in response to the activation of a number of signalling pathways, and that c-Src kinase activity is required for its phosphorylation regardless of the signalling mechanism involved.

The fact that Tyr 845 resides in the activation loop of the kinase domain indicates that phosphorylation of this residue may in some way affect signalling through the EGFR. Recent work from our laboratory has demonstrated that phosphorylation of Tyr 845 is critical for both EGF and LPA induced mitogenesis (Biscardi et al., 1999; Tice et al., 1999). Cells expressing a Y845F mutant form of the EGFR, and either basal levels or overexpressed levels of c-Src, were impaired in their ability to synthesize DNA in response to EGF and serum (Biscardi et al., 1999; Tice et al., 1999). Given the fact that other GPCR and cytokine receptor mediated pathways seem to trigger phosphorylation of EGFR Tyr 845, it is possible that this phosphorylation site may be necessary for mitogenesis in response to these other agonists. To test this hypothesis, cells

overexpressing wild-type c-Src were transiently transfected with either wild type or Y845F EGFR. Following a 24 hour post-transfection recovery period, cells were serum starved for 30 hrs, then incubated with bromodeoxyuridine (BrdU) and one of the panel of agonists for 19 hours. Cells were then processed for double immunofluorescence labelling as described previously (Biscardi et al., 1999; Tice et al., 1999). Fig. 4 shows that expression of a Y845F mutant EGFR resulted in decreased DNA synthesis in response to EGF, as well as to the GPCR ligands LPA and ET. Another GPCR ligand, thrombin, did not appear to be mitogenic in this cell system. The fact that LPA- and ET-induced mitogenesis is dependent on the ability to phosphorylate EGFR Tyr 845 suggests that this phosphorylation site is a common, critical target downstream of a wide variety of mitogenic stimuli.

In addition to being a mediator of signalling resulting from GPCRs and the growth hormone receptor, there is increasing evidence that crosstalk exists between EGF-mediated and estrogen-mediated pathways. It has long been known that EGF is able to induce transcription of estrogen-responsive genes via activation of the AF-1 (ligand-independent) region of the estrogen receptor (Ignar-Trowbridge et al., 1992, 1993). It has been hypothesized that the EGFR triggers activation of the mitogen-activated protein kinase (MAPK), which phosphorylates the estrogen receptor at position 118 in the AF-1 region (Kato et al., 1995; Bunone et al., 1996). More recent work shows that c-Src signalling can be regulated by estrogens. For example, estrogen causes increases in c-Src autophosphorylation and kinase activity in MCF7 breast cancer cells, and the concomitant activation of the MAPK pathway (Migliaccio et al., 1993, 1996, 1998). Moreover, both c-Src kinase activity and MAPK activity were found to be necessary for estrogen-induced proliferation of MCF7 cells (Castoria et al., 1999). An intriguing hypothesis for the crosstalk between estrogen and c-Src kinase pathways could involve the c-Src mediated phosphorylation of EGFR Tyr 845. Since Tyr 845 phosphorylation appears to be a general response to activation of EGF, cytokine, and G protein mediated pathways, it is possible that Tyr 845 phosphorylation may be triggered by estrogen as well.

To test this possibility, MCF7 human breast cancer cells maintained in charcoal stripped serum were transiently transfected with either wild type or Y845F EGFR, serum starved for 30 hours in phenol red free-media, then incubated for 19 hours with BrdU and either EGF or estradiol (3  $\mu$ M). Cells were then processed for double immunofluorescence labelling as described (Tice et al., 1999). MCF7 cells responded mitogenically to both EGF and estrogen (Fig. 5). Moreover, expression of Y845F mutant EGFR resulted in a decrease to basal levels of both EGF- and estradiol-induced DNA synthesis. This result indicates that Tyr 845 phosphorylation is a critical event for estrogen induced mitogenesis. Taken together with the above results, it appears that the c-Src mediated phosphorylation of Tyr 845 is a central event that is crucial for mitogenesis downstream of various G-protein coupled, cytokine, and estrogen receptors.

In addition to studying the role of Tyr 845 phosphorylation in EGFR crosstalk, our laboratory has also begun elucidating which biochemical pathway(s) downstream of Tyr 845 phosphorylation lead to mitogenesis. Initial studies comparing 5HR (which dually overexpress wild type EGFR and c-Src) and 430R cells (which overexpress wild type EGFR and kinase inactive c-Src, and in which EGFR Tyr 845 phosphorylation is not observed) did not reveal any differences in the EGF-dependent

activation/phosphorylation of several signalling molecules downstream of the EGFR including Shc, phospholipase C $\gamma$ , MAPK, STAT3, and PI3-kinase (DA Tice and JS Biscardi, unpublished results). Moreover, COS cells which were transiently transfected with either wild type or Y845F mutant EGFR did not show any differences in EGFR autophosphorylation activity, Shc phosphorylation or MAPK activation (Tice et al., 1999). However, very preliminary evidence shows that the phosphorylation of MAPK, Shc, and c-Cbl, an adapter protein specific to the EGFR signalling pathway, is actually increased in 430R cells versus 5HR cells stimulated with growth hormone and the G protein coupled agonists (data not shown). This unexpected result may hint at the upregulation of alternate signalling pathways in the 430R cells, which are growth-compromised, to compensate for the lack of EGFR Tyr 845 phosphorylation. Thus, it is likely that another, as yet undescribed pathway controls growth downstream of Tyr 845 phosphorylation. Additional preliminary evidence points to a role for STAT5b in regulating signalling downstream of EGFR Tyr 845 phosphorylation, in that decreased EGF-dependent STAT5b phosphorylation is observed in 430R cells with respect to 5HR cells (Silva et al., unpublished results). I am currently collaborating with Corinne Silva, an assistant professor at the University of Virginia, to investigate the mechanism by which c-Src and the EGFR contribute to signalling through STA5b in breast cancer cells.

The last aspect of my work this year deals with elucidating the function of the other c-Src-dependent phosphorylation of EGFR, namely, Tyr 1101. This tyrosyl residue is present in the carboxy terminus of the EGFR, and thus may serve as a docking site for EGFR substrate molecules. In vitro evidence has shown that c-Src can bind a peptide containing a phosphorylated Tyr 1101 via a PTyr/SH2 interaction (Lombardo et al., 1995). Thus, it is intriguing to speculate that upon EGF stimulation, c-Src creates its own binding site on Tyr 1101 of the EGFR. To this end, I have been instructing an undergraduate student in the laboratory, and we have created a Y1101F mutant form of the EGFR. We have expressed this construct in COS cells, and will investigate any possible effects on downstream signal transduction, mitogenesis, and tumorigenesis.

### **Key Research Findings:**

- Phosphorylation of the EGFR can be triggered by agonists besides EGF: namely, those that work through G protein coupled receptors (LPA, ET, THR) and cytokine receptors (GH).
- These agonists are also capable of inducing association between c-Src and the EGFR.
- Tyr 845, a critical residue in the activation lip of the EGFR catalytic domain, becomes phosphorylated in response to a number of agonists including EGF, ET, LPA, and GH.
- C-Src kinase activity is required for the phosphorylation of Tyr 845 to occur downstream of the above stimuli.
- Mutation of Tyr 845 to phenylalanine results in ablation of EGF, LPA, ET and estrogen dependent mitogenesis.

**Fig. 1.** Multiple agonists induce EGFR phosphorylation. 5HR or 430 R cells were treated for 10 min with EGF (100 ng/ml), endothelin (10  $\mu$ M), growth hormone (500 ng/ml), isoproterenol (10  $\mu$ M), lysophosphatidic acid (10  $\mu$ M) or thrombin (2U/ml), lysed in RIPA buffer, and subjected to EGFR immunoprecipitations with Mab F4. Phosphorylated EGFR was visualized by immunoblotting with PTyr antibody RC20 and ECL (Panel A), while overall EGFR was visualized by immunoblotting with EGFR Mab F4 (Panel B). The blot shown is representative of 5 independent experiments.

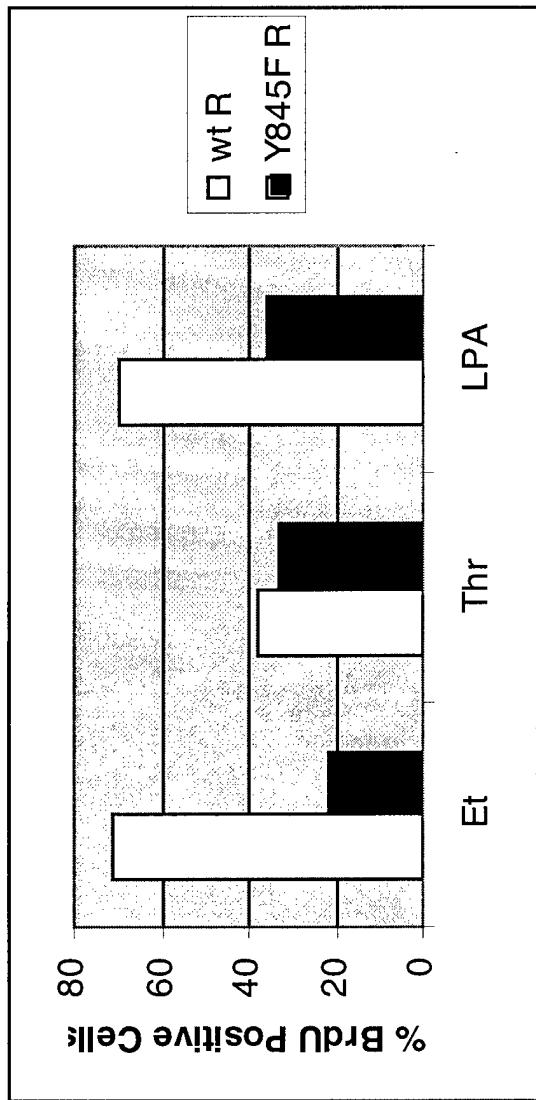

**Fig. 2.** Multiple agonists induce HER1 association with c-Src. 5HR cells were treated for 10 min with EGF (100 ng/ml), endothelin (10  $\mu$ M), growth hormone (500 ng/ml), isoproterenol (10  $\mu$ M), lysophosphatidic acid (10  $\mu$ M) or thrombin (2U/ml), lysed in CHAPS buffer, and subjected to c-Src immunocomplex assays with Mab GD11. The c-Src associated HER1 was visualized by autoradiography. The data shown are representative of 4 independent experiments.

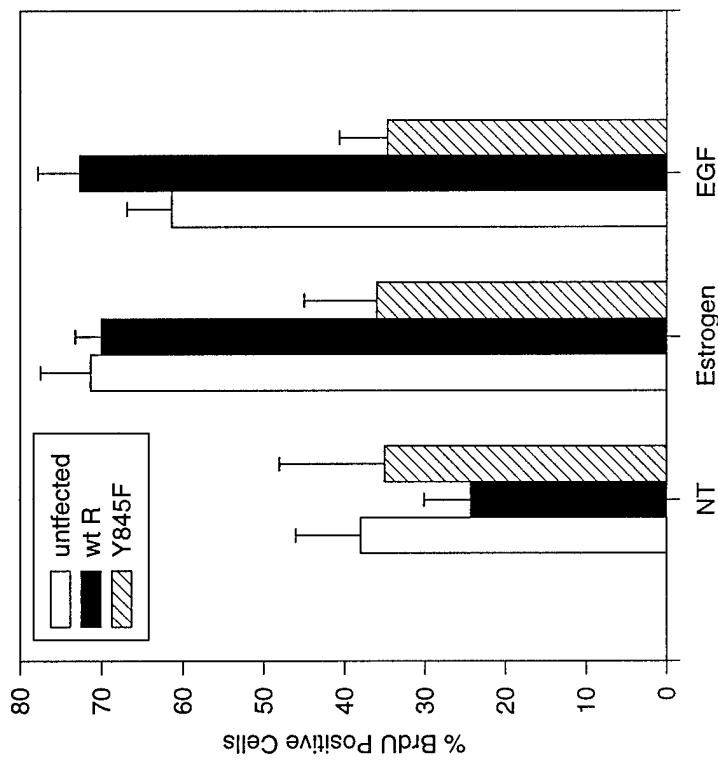

**Fig. 3.** Endothelin, growth hormone, LPA, and EGF all induce phosphorylation of Tyr 845 of the c-Src associated HER1, and this phosphorylation is dependent on c-Src kinase activity. 5HR or 430R cells were processed for *in vitro* immunocomplex kinase reactions as described in the text, and the c-Src associated HER1 was excised and digested with trypsin. The maps shown are representative of 3 independent experiments.

Untreated 5HR cells

**Fig. 4.** Phosphorylation of Tyr 845 is necessary for endothelin and LPA induced mitogenesis. 5H (c-Src overexpressing) cells were transfected with plasmid DNA encoding Y845F or wt EGFR, cultured for 24 hr, serum starved for 30 hr, and left untreated or treated with 10 $\mu$ M endothelin or 10  $\mu$ M LPA for 18 hr. At least 15 cells were analyzed for each variable.

### Estrogen and EGF induced DNA synthesis in MCF7 cells

**Fig. 5.** Phosphorylation of Y845 is essential for EGF and estrogen induced mitogenesis in MCF7 breast cancer cells. MCF7 cells maintained in phenol-red free, charcoal stripped serum-containing media were transfected with plasmid DNA encoding Y845F or wt EGFR, cultured for 24 hours, serum starved for 30 hours, and left untreated or treated with 40 ng/ml EGF or 10  $\mu$ M estradiol for 19 hr. Results are expressed as the mean percent +/- SEM of cells expressing the EGFR that were positive for BrdU incorporation. At least 35 cells were analyzed for each variable in 3 independent experiments.

## INTRODUCTION

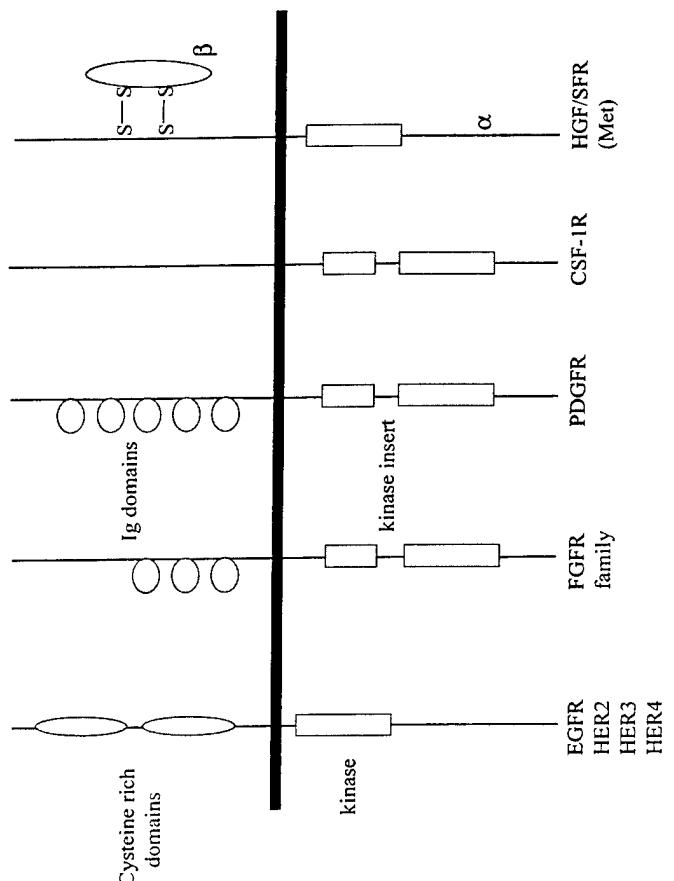

Since the discovery that tyrosine kinases are among the transforming proteins encoded by oncogenic animal retroviruses, it has been speculated that this family of enzymes may contribute to the development of human malignancies. However, evidence supporting that hypothesis has been slow to evolve, largely because early emphasis was placed on examining human tumors for genetic alterations in protooncogenes encoding these enzymes. Such alterations have proved rare or nonexistent. Instead, investigations have fo-

cused on determining levels of expression and posttranslational mechanisms of regulation of these proteins, particularly as they relate to signaling pathways that modulate growth, adhesion, invasion, and motility. Two classes of tyrosine kinases have emerged as potentially important players in promoting the evolution of human tumors: receptor kinases (RTKs) and nonreceptor tyrosine kinases of the c-Src family. Elevated levels of both these classes of tyrosine kinases can be found in a large number of tumors in a strikingly similar pattern of aberrant cooverexpression, suggesting that the two families may cooperate with one another during oncogenesis. Indeed, in model tissue culture systems, overexpression of receptor alone can result in malignant transformation when a continuous source of ligand is provided. However, overexpression of c-Src alone is non- or weakly oncogenic. These results indicate that c-Src, if it plays a role in tumorigenesis, most likely mediates its effects through RTKs. Demonstrations that c-Src physically associates with a number of RTKs in a ligand-dependent fashion provided some of the first evidence for functional cooperativity between these families of proteins. Subsequent studies showed that in complex, the two kinases reciprocally affect one another's behavior, such that c-Src can be regarded both as a regulator of RTKs and as a cotransducer of signals emanating from them. c-Src is capable of physically associating with the receptors for platelet-derived growth factor (PDGF), prolactin, epidermal growth factor (EGF), colony-stimulating factor-1 (CSF-1), fibroblast growth factor (FGF), and hepatocyte growth factor/scatter factor (HGF/SF), as well as with the HER2/neu and Sky tyrosine kinases (this review and Toshima *et al.*, 1995; Berlanga *et al.*, 1995), all of which are postulated to play a role in the genesis and/or progression of various human cancers. Although c-Src and its family members are also known to participate in signaling events elicited by heterotrimeric G protein-coupled receptors (Malarkey *et al.*, 1995) and neuronal ion channels (Ely *et al.*, 1994; Holmes *et al.*, 1994; Yu *et al.*, 1997; van Hoek *et al.*, 1997), this review focuses on the interactions of c-Src and Src family members with RTKs because of the growing documentation of the interactions between these proteins in human malignancies. First, a summary is presented, naming the RTKs that are most frequently implicated etiologically in human cancers and that have been shown to interact with c-Src. This summary includes a short review of the physical characteristics of the receptors, their molecular mechanisms of signaling, and their putative roles in specific cancers. Second, evidence is discussed for the involvement of c-Src and Src family members in human tumor development, and third, a synopsis is outlined showing the molecular mechanisms by which c-Src and its family members have been found to interact with receptors and other targets. Finally, we will speculate on the prospects for developing novel therapies based on these interactions.

## II. RECEPTOR TYROSINE KINASES AND HUMAN CANCERS

Figure 1 depicts the structural features of several classes of RTKs that interact with c-Src. All consist of an extracellular ligand-binding domain that bears motifs characteristic of the type of receptor (e.g., repeated immunoglobulin-like motifs for the PDGF and FGF receptors or cysteine-rich motifs in the EGF family of receptors), a transmembrane segment, a tyrosine

**Fig. 1** Structures of receptor tyrosine kinase families known to associate with c-Src. All receptors are transmembrane glycoproteins that function as receptors for polypeptide growth factors. Structurally, these molecules are composed of large, extracellular domains that exhibit characteristic ligand-binding motifs, as well as transmembrane, juxtamembrane, catalytic, and C-terminal domains. Ligand binding induces dimerization, enzymatic activation, and autophosphorylation on specific tyrosine residues in the C-terminal domains. These phosphorylated tyrosine residues serve as docking sites for signaling molecules that transmit biological signals from the extracellular milieu to the nucleus. In the platelet-derived growth factor (PDGF) and fibroblast growth factor (FGF) receptor families, the kinase domain is interrupted by an insert that contains additional docking sites. EGFR, Epidermal growth factor receptor; CSF-1R, colony-stimulating factor-1 receptor; HGF/SFR, hepatocyte growth factor/scatter factor receptor; HER, human epidermal growth factor receptor.

kinase catalytic domain, and a carboxy-terminal region that contains sites of autophosphorylation. Binding of ligand causes dimerization of the receptors, activation of tyrosine kinase activity, and (trans) autophosphorylation of specific C-terminal tyrosine (Tyr) residues (reviewed in Heldin, 1996; Weiss *et al.*, 1997), which in turn serve as docking sites for a variety of signalling molecules that contain SH2 domains (Pawson and Schlessinger, 1993), including phospholipase C $\gamma$  (PLC $\gamma$ ), phosphatidylinositol-3 kinase (PI-3 kinase), GTPase-activating protein of Ras (RasGAP), phosphotyrosine phosphatases (PTPs), Janus kinases/signal transducers and activators of Transcription (JAK/STATS), adapter proteins (including Shc, Grb, Nck), and members of the c-Src family of tyrosine kinases (reviewed in Erpel and Courtneidge, 1995; Heldin, 1996). Signals are subsequently transmitted to the nucleus via several pathways, including the JAK/STAT and the Grb2/SOS/Ras/Raf/MEK/MAP kinase cascades (reviewed in Bonfini *et al.*, 1996; Denhardt, 1996). Members of the STAT and MAP kinase families translocate from the cytoplasm to the nucleus and induce changes in gene expression, which bring about a variety of functional outcomes, such as mitogenesis, morphogenesis, and motility. The contribution of c-Src to downstream signaling from these RTKs has been the subject of growing interest, with emphasis on how c-Src may contribute to transformation and maintenance of the cancerous phenotype that is dependent on and induced by the receptors.

In this treatise, a total of five RTK families and their putative roles in development of malignancy will be considered. The first four, receptors for HGF/SF, CSF-1, FGF, and PDGF, are implicated as etiological agents in a wide variety of human cancers, and their ability to influence processes such as cytoskeletal changes, cell motility, and angiogenesis are thought to contribute to the metastatic potential of tumors. The fifth group, members of the EGF receptor family (HER1–4), will be discussed in the context of breast cancer, along with the estrogen receptor. This steroid hormone receptor plays a pivotal role in the etiology of breast cancer and growing evidence indicates its ability to reciprocally interact with c-Src and members of the HER family of RTKs.

## A. Hepatocyte Growth Factor/Scatter Factor Receptor

The Met tyrosine kinase is the receptor for hepatocyte growth factor/scatter factor (Bortaro *et al.*, 1991; Naldini *et al.*, 1991). This receptor was first identified as the product of the human oncogene, *tpr-met*, which was isolated from a chemically treated human cell line by the NIH3T3 gene transfer method (Cooper *et al.*, 1984; Park *et al.*, 1987). The normal cellular receptor is composed of two subunits, a 145-kDa  $\beta$  chain, which spans the cell

membrane and possesses ligand-binding and tyrosine kinase activity, and a 50-kDa  $\alpha$  chain, which resides extracellularly and is covalently bound to the  $\beta$  subunit through disulfide linkages (Gonzatti-Haces *et al.*, 1988). Related family members include the Sea and Ron RTKs (Ronsin *et al.*, 1993; Huff *et al.*, 1993). Each member of the Met family possesses two tandemly arranged, degenerate YVH/NV motifs in the C-terminal tail of the receptor, which are capable of binding the SH2 domains of the signaling molecules PI-3 kinase, PIPase 2, PLC $\gamma$ , c-Src, and Grb2/Sos (Ponsetto *et al.*, 1994). Mutations in these motifs (H1351N) result in increased transforming ability but decreased metastasis (Giordano *et al.*, 1997), a phenomenon that is linked to the creation of an additional Grb2 binding site and hyperactivation of the Ras pathway. HGF/SF is produced by cells of mesodermal origin and acts on epithelial and endothelial cells, eliciting numerous biological responses, including cell motility, growth, morphogenesis, differentiation, and angiogenesis (Kan *et al.*, 1991; Rubin *et al.*, 1991; Halabian *et al.*, 1992). Which response is elicited in part depends on the cell type, developmental stage, and tissue context (Weidner *et al.*, 1993; Kanda *et al.*, 1993; Zhu *et al.*, 1994; Rosen and Goldberg, 1995; Grano *et al.*, 1996). For example, Met signals through STAT3 to induce the formation of branched tubule structures in Madin-Darby canine kidney (MDCK) cells, a hallmark of angiogenesis (Boccaccio *et al.*, 1998). HGF binding to primary human osteoclasts and osteoblasts triggers receptor kinase activity and autophosphorylation in both cell types. However, in osteoclasts, HGF binding is accompanied by increased levels of intracellular calcium, activation of c-Src, changes in cell shape, stimulation of chemotaxis, and DNA replication, whereas osteoblasts respond simply by undergoing DNA synthesis (Grano *et al.*, 1996). Furthermore, osteoclasts also express HGF, but osteoblasts do not. This finding suggests that an autocrine loop may be responsible for signaling in osteoclasts, whereas a paracrine mechanism is functional in osteoblasts.

HGF/SF and the Met receptor have been implicated in several types of human cancer. Met is overexpressed in gastric, ileal, colorectal, and thyroid papillary carcinomas, as well as in osteogenic sarcoma (Di Renzo *et al.*, 1991, 1992; Rosen *et al.*, 1994; Grano *et al.*, 1996). The level of Met expression, as measured by intensity of Met immunofluorescence, has also been shown to correlate with grade of malignancy in primary human brain tumors (Koochekpour *et al.*, 1997). In the case of ovarian carcinoma, Met levels can be regulated by the cytokines interleukin 1 $\alpha$  (IL-1 $\alpha$ ), IL-6, and tumor necrosis factor  $\alpha$  (TNF $\alpha$ ), thereby providing a physiological mechanism by which overexpression of Met can be achieved (Moghul *et al.*, 1994). Approximately 14% of patients with papillary renal carcinoma have germ-line alterations in the Met receptor (Schmidt *et al.*, 1997). Receptors bearing these mutations have been shown in NIH3T3 cells to result in increased tyrosine kinase activity of the receptors and Met-mediated focus formation

and tumors in nude mice, thus providing direct evidence for the ability of mutationally altered Met to function as an oncogene (Jeffers *et al.*, 1997). The ability of HGF/SF to "scatter" cells and to increase their motility is strongly suggestive of a role for this ligand in tumor cell invasion. Indeed, several lines of evidence link HGF/SF to stimulation of the urokinase plasminogen activator (UPA) system, a cascade of proteases thought to promote release, extravasation, and migration of tumor cells. That the UPA cascade is critical for cell migration is supported by the findings that UPA<sup>-/-</sup> mice are unable to recruit migrating cells in response to inflammation (Gyetko *et al.*, 1996), and do not support the growth and metastasis of experimental melanomas (Min *et al.*, 1996). Shapiro *et al.* (1996) also showed that blocking interaction of UPA with its receptor results in decreased angiogenesis and tumor spread. The link between UPA and HGF was made when Jeffers *et al.* (1996b) reported that stimulation of the urokinase proteolytic system occurred concomitantly with HGF/SF-induced invasion and metastasis of human tumor cells. Rosen and Goldberg (1995) also demonstrated that HGF/SF is capable of stimulating angiogenesis in a rat cornea neovascularization assay. Together, these studies provide compelling evidence that HGF/SF are capable of promoting tumor progression by enhancing invasion and angiogenesis.

Further evidence for a role for HGF/SMet receptor in tumor invasiveness and angiogenesis comes from the findings that high titers of HGF/SF in invasive breast cancers are factors for relapse and death (Yamashita *et al.*, 1994), that HGF/SF treatment of glioma cell lines stimulates proliferation and invasion (Koochekpour *et al.*, 1997), and that invasive bladder carcinomas possess higher HGF/SF titers than do noninvasive cancers (Joseph *et al.*, 1995). In addition, the Met receptor is overexpressed in several types of tumor stroma, including bladder wall, vascular smooth muscle, and vascular endothelial cells (Rosen and Goldberg, 1995), suggesting a paracrine signaling mechanism between tumor cells and the underlying stroma. Thus, HGF/SF and Met interactions may promote metastasis by enhancing proliferation via autocrine or paracrine routes, stimulating the expression of plasminogen activators, and triggering angiogenesis. (Rong *et al.*, 1992; Kanda *et al.*, 1993; Bellusci *et al.*, 1994; Jeffers *et al.*, 1996a,b).

shown by studies in mice that fail to express functional CSF-1: these mice exhibit an osteopetrotic phenotype and lack osteoclasts and macrophages (Wiktor-Jedrzejczak *et al.*, 1990, 1991). The CSF-1 receptor is expressed in placenta (Pollard *et al.*, 1987; Regenstreif and Rossant, 1989; Hume *et al.*, 1997), osteolasts (Insogna *et al.*, 1997), and cells of monocyte lineage (Woolford *et al.*, 1985), whereas the ligand, CSF-1, is produced by fibroblasts, myoblasts, osteoblasts, bone marrow stromal cells, and endothelial cells (Sherr, 1990; Roth and Stanley, 1992). Such independent distribution of ligand and receptor underlies the importance of cell-cell interactions in regulating receptor function.

c-Fms bears sequence and structural similarity to the *steel* receptor, c-Kit, and to the receptors for FGF, PDGF, and Flt3/FLK2 (Hanks *et al.*, 1988; Rosnet and Birnbaum, 1993). The unique feature of this group is that each member possesses an "insert" region within its kinase domain. The downstream targets of c-Fms include PI-3 kinase, STAT 1, and PLCγ, all of which bind to phosphorylated tyrosine residues within the kinase insert portion of the molecule (Varttovski *et al.*, 1989; Shurtliff *et al.*, 1990; Reedijk *et al.*, 1990; Novak *et al.*, 1996; Bourette *et al.*, 1997). Bourette *et al.* (1997) have shown that sequential activation of the PI-3-kinase-dependent and PLCγ-dependent signalling pathways is required to initiate the differentiation process of myeloid cells. c-Src has also been shown to associate with c-Fms and to be activated on binding of CSF-1 to the receptor. Complex formation between c-Src and c-Fms is thought to occur via the SH2 domain of c-Src and a juxtamembrane phosphotyrosyl residue on the receptor (Courtneidge *et al.*, 1993; Alonso *et al.*, 1995). In osteolasts, phosphorylation of c-Src in response to CSF-1 stimulation occurs concomitantly with rearrangements of the actin cytoskeleton and spreading of the cells, suggesting that c-Src may be involved in regulating these processes (Insogna *et al.*, 1997).

Overexpression of c-Fms in NIH3T3 or Rat2 fibroblasts or in various tumor cells results in transformation, growth in soft agar, and tumor formation in nude mice (Rettenmeier *et al.*, 1987; Taylor *et al.*, 1989; van der Geer and Hunter, 1989; Favot *et al.*, 1995). These findings demonstrate the oncogenic potential of overexpressed c-Fms. As described above, c-Fms and CSF-1 are normally not expressed in the same cell type. However, coexpression is seen in tumors of the pancreas, endometrium, stomach, lung, and breast, and in acute myeloid leukemia, hairy cell leukemia, and Hodgkin's lymphoma (Rambaldi *et al.*, 1988; Kacinski *et al.*, 1990; Paietta *et al.*, 1990; Baiocchi *et al.*, 1991; Kauma *et al.*, 1991; Bruckner *et al.*, 1992; Fildeerman *et al.*, 1992; Storga *et al.*, 1992; Tang *et al.*, 1992; Leiserowitz *et al.*, 1993; Till *et al.*, 1993; Burthem *et al.*, 1994; Berchuck and Boyd, 1995). Coexpression correlates with poor patient prognosis, most likely due to the establishment of an autocrine loop (Kacinski *et al.*, 1990; Tang *et al.*, 1992). Evidence suggests that such an autocrine loop contributes not only to tumor

## B. Colony-Stimulating Factor-1 Receptor

c-Fms, the cellular homolog of the viral oncogene v-Fms (Sherr *et al.*, 1985), is the receptor for colony-stimulating factor-1, which stimulates the proliferation and differentiation of macrophages, osteoclasts, and plasmacytrophoblasts (Sherr, 1990; Roth and Stanley, 1992; Insogna *et al.*, 1997). That CSF-1 is critical for the development of mononuclear phagocytes was

cell proliferation but also to invasiveness (Bruckner *et al.*, 1992; Fidderman *et al.*, 1992; Burthem *et al.*, 1994). In this regard, coexpression of c-Fms and its ligand in endometrial cancers correlates with a more advanced stage and with increased myometrial invasion (Leiserowitz *et al.*, 1993). Moreover, CSF-1 stimulation results in the expression of UPA in lung tumors, Lewis lung carcinoma cells, and in NIH3T3 cells transfected with c-Fms (Fidderman *et al.*, 1992; Favor *et al.*, 1995; Stacey *et al.*, 1995). Together, these findings suggest that, like HGF/SF/MetR, deregulation of c-Fms/CSF-1 interactions has the potential of contributing to the metastatic process in a variety of human cancers.

### C. Fibroblast Growth Factor Receptors

The FGF receptors comprise a large family that is encoded by four separate genes, each of which can be alternatively spliced. Each receptor is also capable of binding several different ligands, resulting in a complex array of possible receptor/ligand pairs (Johnson and Williams, 1993). All receptors for FGF possess extracellular ligand-binding domains, which contain immunoglobulin-like repeats, and bipartite, intracellular tyrosine kinase domains (Lappi, 1995). Which signaling molecules are recruited varies with cell type and receptor/ligand pair. For example, in NIH3T3 cells (Zhan *et al.*, 1994) FGFR 1 and c-Src physically associate following ligand binding, and activation of the receptor triggers the c-Src-dependent phosphorylation of the actin-binding protein, cortactin. Because cortactin is localized to cortical actin, particularly at the leading edge of a migrating cell (Wu *et al.*, 1991; Maa *et al.*, 1992; Wu and Parsons, 1993), its phosphorylation is speculated to influence cell motility and invasiveness. In other studies, ligand stimulation of FGFR 1 and FGFR 3 on C6 rat myoblasts results in activation of the p21Ras and MAPK pathway (Klint *et al.*, 1995; Kanai *et al.*, 1997). In these same cells, activation of the FGFR 3 receptor alone causes an increase in phosphorylation of PLC $\gamma$  but a decrease in c-Src phosphorylation (Kanai *et al.*, 1997).

FGF receptors are ubiquitously expressed during embryogenesis, but their presence is restricted after birth (Wanaka *et al.*, 1991; Peters *et al.*, 1992, 1993; Pastone *et al.*, 1993). As a family, FGFs have mitogenic, nonproliferative, and antiproliferative effects. Which response is elicited is determined by the ligand, the type of cell exposed to the ligand, and the particular isoform of the receptor expressed on that cell (Schweigerer *et al.*, 1987; Sporn and Roberts, 1988). For example, FGF 2 promotes survival of cultured neurons (Wallick, 1988), whereas FGF 1 and FGF 2 stimulate growth of fibroblasts, oligodendrocytes, astrocytes, smooth muscle cells, endothelial

cells, and retinal epithelial cells (Burgess and Maciag, 1989). FGFs can also act as chemotactic factors for fibroblasts and glial cells (Senior *et al.*, 1986). Basic FGF (bFGF, or FGF 2) induces neurite outgrowth in embryonic chick ciliary ganglion cells (Schubert *et al.*, 1987) and can mediate cellular migration in experimental systems (Sato and Rifkin, 1988). Treatment of cultured vascular endothelial cells with FGF 2 induces the formation of blood capillary-like tubules, a finding that suggests FGFs may play a role in angiogenesis (Montesano *et al.*, 1986; Slavin, 1995). In this regard, a large literature is beginning to accumulate in support of a role for FGFs in angiogenesis, because they have been demonstrated to stimulate endothelial cell division, migration, release of proteolytic enzymes, and capillary formation (Slavin, 1995).

In addition to these functions in normal cells, FGFR family members are implicated in the progression of a variety of human cancers. FGFs are thought to act as autocrine growth factors for melanomas, gliomas, and meningiomas (Lappi, 1995), and their levels are elevated in many different tumor types (Nguyen *et al.*, 1994). FGF receptors are also overexpressed in human tumors. For example, 10% of human breast tumors exhibit amplifications of chromosomal regions encoding FGF receptors (Adnane *et al.*, 1991), and FGFR 4 mRNA levels are frequently elevated in breast cancer cells as compared to normal tissue (Lehtola *et al.*, 1993; Ron *et al.*, 1993; Penault-Llorca *et al.*, 1995). Some evidence also suggests that differential expression of FGFR isoforms can influence the propensity of a cell to undergo malignant transformation. In normal fetal and mature brain, FGFR 1, which possesses three immunoglobulin-like extracellular repeats, is expressed. However, in astrocytic tumors, an increase in the expression of an FGFR with two immunoglobulin-like domains is observed. This form has increased affinity for acidic and basic FGF (Shing *et al.*, 1993). Changes in FGFR expression also occur during the conversion of normal or hyperplastic prosthetic epithelium to malignant tumor tissue, where the increased expression of an alternatively spliced form of FGFR 2, which has a higher affinity for bFGF, appears to create an autocrine stimulatory loop (Wang *et al.*, 1995). FGFs, along with other factors, are often secreted by tumors, and their increased extracellular abundance is linked to enhanced invasiveness (Klagsbrun *et al.*, 1976; Libermann *et al.*, 1987; Wadzinski *et al.*, 1987; Folkman *et al.*, 1988). In breast tumor cells, FGFR 4 activation results in membrane ruffling, a morphological change that is associated with metastasis (Johnston *et al.*, 1995). In *in vitro* invasion assays, FGF 2 induces the migration of bovine capillary endothelial cells through placental tissue in a dose-dependent manner (Mignatti *et al.*, 1989), and bFGF stimulates production of metalloproteinases in human bladder cancer cell lines, an event associated with increased invasiveness of the cells (Miyake *et al.*, 1997). Moreover,

BFGE-dependent, sustained activation of MAPK correlates with the scattering of neuroepithelioma cells (van Puijenbroek *et al.*, 1997). Together, these studies suggest that FGFs and FGFRs play important roles in human cancer progression by promoting the metastatic process.

## D. Platelet-Derived Growth Factor Receptor

The PDGFR has two isoforms,  $\alpha$  and  $\beta$ , which differ in their preferences for binding homo- or heterodimers of the A and B forms of the PDGFR ligand (Yarden *et al.*, 1986; Claesson-Welsh *et al.*, 1989; Claesson-Welsh and Heldin, 1989; Heldin and Westermark, 1990; Ross *et al.*, 1990; Matsui *et al.*, 1993). Both receptor isoforms consist of an extracellular domain that contains immunoglobulin-like motifs, transmembrane and juxtamembrane regions, a catalytic domain with an insert, and a C-terminal tail (Heldin and Westermark, 1990; Ross *et al.*, 1990). Signaling molecules, which include PI-3 kinase (Kazlauskas and Cooper, 1989; Auger *et al.*, 1989; Coughlin *et al.*, 1989), PLC $\gamma$  (Kumjian *et al.*, 1989; Meisenhelder *et al.*, 1989; Wahl *et al.*, 1989; Morrison *et al.*, 1990), RasGAP (Molloy *et al.*, 1989; Kaplan *et al.*, 1990; Kazlauskas *et al.*, 1990), and the Src family members c-Src, Fyn, and c-Yes (Kypta *et al.*, 1990) (Twamley *et al.*, 1992), bind phosphorylated tyrosine residues in the C-terminal tail, the kinase insert, and the juxtamembrane region via their SH2 domains.

Interestingly, the same downstream effectors in different cell types can elicit different cellular responses. For example, in human hepatoma cell lines, PLC $\gamma$  and PI-3 kinase can independently transmit mitogenic signals (Valius and Kazlauskas, 1993), whereas in CHO cells a precise balance exists between migration-promoting signaling via PLC $\gamma$  and PI-3 kinase and migration-inhibitory signaling via RasGAP (Kundra *et al.*, 1994). Phosphorylation of Tyr-988 in the carboxy terminus of the  $\alpha$  receptor is associated with induction of chemotaxis, whereas phosphorylation of Tyr-768 and Tyr-1018 negatively regulates this process (Yokote *et al.*, 1996). These results suggest that the different phosphorylation sites serve as binding sites for unique signaling molecules that influence cellular behavior in different ways. This hypothesis is further supported by studies in smooth muscle cells showing that PDGF-induced activation of PLC $\gamma$  is associated with actin disassembly and chemotaxis, whereas an independent signaling pathway, probably involving small GTPases such as Rho, appears to mediate the proliferative effect of PDGF in this system (Bornfeldt *et al.*, 1995).

PDGF receptors and their ligands regulate a wide spectrum of normal cellular processes in cells of mesenchymal and endothelial origin. These processes include differentiation, proliferation, survival, and migration. For example, the receptor for PDGF  $\alpha$  is necessary for the development of neur-

al crest cells (Soriano, 1997) and alveolar branching in the lung (Souza *et al.*, 1995); the PDGF  $\beta$  receptor is required for proper development of the cardiovascular and renal systems (reviewed in Bershtoltz, 1995). The PDGF  $\beta$  receptor is also found in mesenchymal tissue of the developing trachea and intestine and in the endothelium of blood vessels, where it is thought to play a role in regulating mesenchymal–epithelial interactions (Shimbrodt *et al.*, 1994). In addition, the PDGF  $\alpha$  receptor is required for the maximal chemotactic effect of PDGF on lung fibroblasts (Osornio-Vargas *et al.*, 1996).

Numerous studies suggest that various PDGF and PDGFR isoforms are also involved in the genesis or maintenance of human cancers. The PDGFR is overexpressed in human pancreatic cancer (Ebert *et al.*, 1995), primary and metastatic melanomas (Barnhill *et al.*, 1996), and in mesothelioma cell lines (Versnel *et al.*, 1994; Langerak *et al.*, 1996). PDGFR expression is also seen in many neural crest-derived human tumors, including neuroblastoma and Ewing's sarcoma (Matsui *et al.*, 1993), in basal cell carcinoma (Ponten *et al.*, 1994), and in tumors of the lung and pituitary (Leon *et al.*, 1994; Viagrad *et al.*, 1994). PDGF and its receptors are not normally expressed in epithelial cells, but their aberrant expression in tumors of this origin suggest that they could be involved in the oncogenic process.

The situation is made more complex by the fact that some tumors express one or both forms of the ligand and no receptor(s) or vice versa, suggesting that both autocrine and paracrine signaling loops are involved in PDGF-mediated growth of tumors. For example, autocrine signaling loops have been shown to contribute to the growth of human esophageal carcinomas (Juang *et al.*, 1996), mesotheliomas (Langerak *et al.*, 1996), malignant melanomas (Barnhill *et al.*, 1996), gliomas, and glioblastomas (Potapova *et al.*, 1996). However, results from Coltrera *et al.* (1995) show that PDGF may also function in a paracrine fashion in some human breast tumors. Their studies revealed that PDGF  $\beta$  is expressed in breast epithelium and tumor tissues, and the receptor is present in stromal fibroblasts. A similar situation appears to exist in ovarian cancer (Versnel *et al.*, 1994), in lung tumors (Vignaud *et al.*, 1994), and in basal cell carcinomas (Ponten *et al.*, 1994). The ability of PDGF to induce chemotaxis may also play a role in tumor cell metastasis. For example, expression of the receptor for PDGF  $\alpha$  in Lewis lung carcinoma cells increases their metastatic potential, whereas expression of the receptor truncated at the kinase domain reverses this effect (Fitzer-Attas *et al.*, 1997). Potapova *et al.* (1996) demonstrated that in human glioblastoma cells, which express both the PDGF  $\beta$  receptor and its ligand, further expression of PDGF  $\beta$  results in tumor formation in nude mice and increased metastasis. These examples support the idea that in addition to mediating normal cell migration, aberrant expression or activation of PDGF receptors in tumor cells can contribute to their proliferative and invasive properties.

## E. Epidermal Growth Factor Receptor

The human epidermal growth factor receptor, HER1, belongs to a family of human RTKs that includes HER2/neu, HER3, and HER4 (Ullrich and Schlessinger, 1990). All members of this family are transmembrane tyrosine kinases that possess an extracellular domain with two cysteine-rich repeats, an intact catalytic domain, and a C-terminal tail that binds SH2-containing signaling effectors on activation of the receptor. Ligands for HER1 include epidermal growth factor (EGF), transforming growth factor- $\alpha$  (TGF- $\alpha$ ), betacellulin (Riese *et al.*, 1996), and epiregulin (Komurasaki *et al.*, 1997). No specific ligand for HER2 has yet been defined, but HER3 and HER4 can be activated by a family of alternatively spliced ligands, called heregulins (HRG) (reviewed in Hynes and Stern, 1994). Each member of the HER family is capable of heterodimerizing with other members of the family, thereby providing a means by which HER2, although it lacks a ligand, can signal. Such dimerization appears to occur in a hierarchical order, wherein the HER2/3 interaction is the most preferred and the HER1/4 interaction the least preferred (Pinkas-Kramarski *et al.*, 1996). Studies in 3D hematopoietic cells, which do not express any HER family members, show that heterodimers have more potent mitogenic activity than do homodimers and that HER3 heterodimers are the most transforming. However, when HER1 is present, signaling through this receptor dominates over other members of the family (Pinkas-Kramarski *et al.*, 1996).

The focus of our discussion will be on the roles of HER1 and HER2 in human cancer, because large bodies of literature exist for each. HER3 and HER4 are more recent additions to the family, and characterization of them with respect to their possible involvement in human cancers is just beginning. However, it is important to note that overexpression of HER3 has been detected in some breast cancers (Lemoine *et al.*, 1992) and in papillary thyroid carcinomas (Falksvag *et al.*, 1996). Thus, the possibility exists that homo- or heterodimerization of HER3 or HER4 with HER1 or HER2 mediates tumorigenic signaling in a manner similar to that of HER1 and HER2. A major role for HER1 is its involvement in normal human development. It affects many stages, from postertilization to sexual maturation. For example, HER1 and its ligand, TGF- $\alpha$ , control proliferation of blastocel cells as well as embryo/uterine signaling and implantation (Rappoll *et al.*, 1988; Dardik and Schultz, 1991; Arrholdt *et al.*, 1991; Zhang *et al.*, 1992). HER1 is also necessary for development of embryonic lung, skin, palate (Lee and Han, 1990), and hair follicles (Hansen *et al.*, 1997). During puberty, HER1 and the estrogen receptor together regulate the differentiation of normal breast epithelium and uterine and vaginal growth (Nelson *et al.*, 1991; Ignar-Trowbridge *et al.*, 1992). Loss of control of these interactions is thought to play a role in the genesis of human tumors, and the diversity of tissues

that are regulated developmentally by HER1 is reflected in the spectrum of tissues and cell types in which HER1 is thought to play an oncogenic role.

That HER1 can function as an oncoprotein was demonstrated by the ability of NIH3T3 cells, engineered to overexpress HER1 and held in the continual presence of EGF, to become transformed and develop tumors in nude mice (Velu *et al.*, 1987; DiFiore *et al.*, 1987a; Di Marco *et al.*, 1989). HER1 effector substrates include the adaptor proteins Shc (Pellicci *et al.*, 1992; Ruffinamison *et al.*, 1993) and Grb2, which feed into the well-defined Ras/MAPK signalling pathway (Li *et al.*, 1993; Egan *et al.*, 1993; Rozakis-Adcock *et al.*, 1993), as well as PLC $\gamma$  (Rhee, 1991), c-Cbl (Levkowitz *et al.*, 1996), eps 8, and eps 15 (Fazioli *et al.*, 1992, 1993a,b). Reports from several laboratories show that on activation, HER1 physically associates with the c-Src non-receptor tyrosine kinase in both normal fibroblasts and in a variety of tumor cell lines (Luttrell *et al.*, 1994; Maa *et al.*, 1995; Sato *et al.*, 1995; Stover *et al.*, 1995; Biscardi *et al.*, 1998a). Complex formation with c-Src occurs concomitantly with enhanced phosphorylation of receptor substrates, suggesting that c-Src may act to increase the receptor's tyrosine kinase activity, thus enhancing the potential for cellular transformation and tumorigenesis (Maa *et al.*, 1995; Tice *et al.*, 1998; Biscardi *et al.*, 1998a,b). This hypothesis was tested directly using a panel of C3H10T1/2 murine fibroblasts that were engineered to overexpress HER1 and c-Src, either alone or in combination. Cells overexpressing both HER1 and c-Src were found to produce synergistically larger and more numerous tumors in nude mice and colonies in soft agar than those produced by cells overexpressing either HER1 or c-Src alone (Maa *et al.*, 1995). These findings represent the first causal evidence for co-operativity between c-Src and HER1 in tumorigenesis.

What is the evidence for involvement of HER1 in the genesis of human tumors? Aberrant expression, overexpression, or truncation of HER1 has been demonstrated to occur in a variety of human cancers, including benign skin hyperplasia, glioblastoma, and cancers of the breast, prostate, ovary, liver, bladder, esophagus, larynx, stomach, colon, and lung (Harris *et al.*, 1992; Khazaie *et al.*, 1993; Scambia *et al.*, 1995). In patients with ovarian cancer, overexpression of HER1 correlates with a decreased response to chemotherapy and decreased survival (Scambia *et al.*, 1995; Fischer-Colbrie *et al.*, 1997), suggesting that HER1 plays a proactive role in ovarian tumor progression.

HER1 overexpression also appears to play a role in the etiology of glioblastomas. Forty percent of glioblastomas exhibit amplification of the HER1 gene (Khazaie *et al.*, 1993), but in these tumors, overexpression is not the only abnormality regarding HER1. An alternatively spliced form of the receptor, termed EGFRVIII, is also frequently observed (Libermann *et al.*, 1985; Yamazaki *et al.*, 1988; Tuzi *et al.*, 1991; Chaffanet *et al.*, 1992). This form of the receptor lacks nucleotides 275–1075, which encode a large

portion of the extracellular domain (Humphrey *et al.*, 1990; Ekstrand *et al.*, 1992; Wong *et al.*, 1992), and displays constitutive activity, perhaps due to its inability to be controlled by ligand (Ekstrand *et al.*, 1994). Existing evidence suggests that EGFRvIII signals differently than wild-type receptor, preferring the PI-3 kinase pathway (Moscatello *et al.*, 1998) to the Ras/MAPK pathway (Montgomery *et al.*, 1995; Moscatello *et al.*, 1998). In addition to glial tumors, one study showed that EGFRvIII is present in 16% of non-small-cell lung carcinomas (Garcia *et al.*, 1993) as well as in 86% of medulloblastomas, 78% of breast cancers, and 73% of the ovarian cancers examined (Moscatello *et al.*, 1995). In contrast, EGFRvIII has not yet been detected in normal tissue, a finding that provides compelling evidence for an oncogenic role for this form of the receptor.

A link between HER1 and breast cancer has also emerged in recent years. Amplification or overexpression of the genes encoding one or more of the HER family members is estimated to occur in approximately 67% of human breast cancers (Harris *et al.*, 1992), with overexpression of HER1 detected in approximately 30% of patients (Bartaglia *et al.*, 1988; Delarue *et al.*, 1988; Bolla *et al.*, 1990; Koenders *et al.*, 1991; Toi *et al.*, 1991; Harris *et al.*, 1992). Elevated levels of HER1 are also associated with loss of estrogen-dependent growth (Klijn *et al.*, 1993), suggesting a role for HER1 in the later stages of tumor progression.

In addition to transformation and proliferation, studies from several laboratories suggest that HER1 also enhances the invasive potential of tumor cells. Overexpression of HER1 has been shown to result in an increased ability of rat mammary carcinoma cells to migrate through matrigel (Lichtner *et al.*, 1995; Kaufmann *et al.*, 1996), and higher levels of HER1 are found in tumor tissue at metastatic sites as compared to primary sites (Sainsbury *et al.*, 1987; Toi *et al.*, 1991). Both these findings are supportive of a role for HER1 in metastasis.

## F. HER2/neu

Like HER1, activated HER2 possesses an intracellular tyrosine kinase domain as well as C-terminal phosphorylation sites that are capable of binding downstream substrates, such as PLC $\gamma$ , PI-3 kinase, Grb7, p120 RasGAP, p190, RhoGAP, c-Src, Shc, PTP1D, PTP1B, eps-8, and Tob, an antiproliferative protein (Hynes and Stern, 1994; Matsuda *et al.*, 1996; Liu and Chernoff, 1997). Because both HER1 and HER2 appear to activate similar downstream signaling pathways in experimental cell systems, it is unclear how specificity of signaling is achieved. The most likely explanation is that activation of a particular signaling pathway is dependent on cell type and on the

subset of HER family members and effector molecules available at any given time. However, a few examples of specific substrates have been reported, such as the c-Cbl adaptor protein for HER1 (Levkowitz *et al.*, 1996) and paxillin and a protein of 23 kDa (p23) for HER2 (Romano *et al.*, 1994). HER2 is expressed in all tissues except the hematopoietic system (De Peter *et al.*, 1990; Press *et al.*, 1990). Studies using mice that are deficient in HER2, HER4, or the HER3/4 ligand, HRG, demonstrate that signaling through HER2 heterodimers is necessary for proper cardiac and neural development (Meyer and Birchmeier, 1995; Gassmann *et al.*, 1995; Lee *et al.*, 1995). A great deal of evidence from both experimental systems and human patients also points to the involvement of HER2 in malignant transformation. In certain tumors, it has been found that HER2 can be overexpressed up to 100 fold, due to gene amplification (Hynes and Stern, 1994). This finding, coupled with the fact that overexpression of HER2 alone, without the addition of agonist for HER family members, can induce focus formation in cultured fibroblasts (Hudziak *et al.*, 1987; DiFiore *et al.*, 1987b) suggests that overexpression of HER2 is capable of inducing oncogenic activity in the human. In addition, overexpression of HER2/neu in PC-3 prostate cancer cells has been shown to result in an increased incidence of metastasis after orthotopic introduction (Zhau *et al.*, 1996). Whereas amplification of the gene encoding HER2 is found in 10–30% of breast, ovarian, and gastric tumors (Hynes and Stern, 1994), tumors of the lung, mesentery, bladder, and esophagus contain high levels of HER2 protein but no gene amplification, suggesting that both transcriptional and posttranscriptional mechanisms are responsible for increased HER2 levels (Kraus *et al.*, 1987; Hynes *et al.*, 1989; King *et al.*, 1989; Kameda *et al.*, 1990).

HER2 is apparently involved in the genesis of many types of human tumors, but its role has been most well-characterized in breast cancer. Increased levels of HER2 protein appear to correlate with poor patient prognosis (Slamon *et al.*, 1987, 1989; Paik *et al.*, 1990; Gusterson *et al.*, 1992) and a loss of responsiveness to the antiestrogen, tamoxifen (Nicholson *et al.*, 1990; Wright *et al.*, 1992; Klijn *et al.*, 1993). In transgenic mouse models, HER2/neu was demonstrated to induce mammary tumors when expression was targeted to the mammary gland by the use of the murine mammary tumor virus promoter (Muthuswamy *et al.*, 1994). These HER2/neu tumors contain increased levels of c-Src and c-Yes kinase activity as compared to normal, surrounding tissue (Muthuswamy *et al.*, 1994; Muthuswamy and Muller, 1995). Furthermore, c-Src was found to coimmunoprecipitate with HER2/neu (Muthuswamy *et al.*, 1994), suggesting that c-Src cooperates with HER2 as well as with HER1 in regulating malignant progression. Because HER2/neu is most frequently localized to the primary tumor mass in the murine model and is found in earlier stage *in situ* carcinomas in humans

(van de Vijver *et al.*, 1988; Paik *et al.*, 1990; Lin *et al.*, 1992; Barnes *et al.*, 1992), it is speculated that this molecule is involved in earlier stages of breast cancer than is HER1.

## G. HER Family Members and Estrogen Receptor Interactions

Increasingly compelling data are accumulating that point to interactions among the estrogen receptor (ER), HER1, HER2, and c-Src as being major factors in the development of human breast cancer. The ER is a steroid hormone receptor of 67 kDa that dimerizes and becomes activated as a transcription factor on binding of estrogen (Mangelsdorf *et al.*, 1995). Functional domains of the ER include an amino-terminal A/B region, which is responsible for ligand-independent transcriptional activation; a central DNA-binding domain; and a carboxy-terminal E/F hormone-binding domain, which is responsible for estradiol-induced transcription (Tsai and O'Malley, 1994; Beato *et al.*, 1995). In addition to the well-characterized ER  $\alpha$  isoform, a  $\beta$  isoform, which has differing transcriptional properties and expression patterns, has been discovered (Paech *et al.*, 1997).

Loss of ER responsiveness in human breast tumors correlates with overexpression of HER1 and with a poorer patient prognosis (Fitzpatrick *et al.*, 1984; Sainsbury *et al.*, 1985; Davidson *et al.*, 1987; Nicholson *et al.*, 1988). The mechanism by which a breast tumor cell loses responsiveness to estrogen is unclear, but this event may be regulated in part by interactions with HER family members and/or c-Src. Cross-talk between growth factor receptor tyrosine kinases and the ER was first demonstrated by Ignar-Trowbridge and co-workers (1992, 1993), who showed that treatment of cells with EGF activates the transcriptional activity of the ER and that this effect is dependent on the amino-terminal A/B domain of the ER. The ER also appears to have the ability to affect expression of the EGF receptor. In ER-positive breast cancer cells, estradiol treatment increases HER1 mRNA levels (Yarden *et al.*, 1996). This effect may be directly mediated by the ER, because the HER1 promoter has sequences that share loose homology with the estrogen response element (ERE) and can bind human ER (Yarden *et al.*, 1996).

Conversely, HER1 can affect ER expression. Overexpression of TGF- $\alpha$  in the ER-positive ZR75-1 breast cancer cell line, along with prolonged treatment of these cells with antiestrogens, results in loss of the ER, whereas treatment of parental ZR75-1 cells with antiestrogens alone has little effect (Clarke *et al.*, 1989; Agrhoven *et al.*, 1992). These results are interpreted to mean that continual and concomitant stimulation of HER1 and ER can cause a reduction in ER expression. In this regard, it is through that expres-

sion of HER1 and ER and mutually exclusive, because most breast tumors that overexpress HER1 lack functional ER (Fitzpatrick *et al.*, 1984; Sainsbury *et al.*, 1985; Davidson *et al.*, 1987; Nicholson *et al.*, 1988). Because breast tumors that do not show this inverse expression tend to be HER1/ER positive rather than HER1/ER negative, it has been suggested that overexpression of HER1 precedes loss of the ER (Koenders *et al.*, 1991; Dittadi *et al.*, 1993; Chrysogelos and Dickson, 1994).

It is unclear how overexpression or activation of HER1 leads to loss of ER expression. One possible mechanism may involve signaling to MAP kinase. HER1 activation results in the phosphorylation of the ER on Ser-118, a phosphorylation that is required for hormone-independent transcriptional activity of the ER (Kato *et al.*, 1995). Ser-118 is also thought to be a target for MAP kinase, because studies using dominant negative Ras and MEK demonstrated a loss of this phosphorylation concomitantly with a loss of EGFR-dependent transcriptional activation (Bunone *et al.*, 1996). Autocrine stimulatory loops involving TGF- $\alpha$  and HER1 are known to exist in breast cancer, thus it is speculated that the continued stimulation of the ER via the HER1/MAP kinase pathway leads to its down-regulation and eventual loss. Estradiol is also known to induce phosphorylation of the ER (Auricchio *et al.*, 1987). In addition, Arnold *et al.* (1995a) reported that the ER is basally phosphorylated on Y537 *in vivo*. The role of the Y537 phosphorylation is controversial. Early studies showed that tyrosine phosphorylation of the ER activates its hormone-binding activity (Migliaccio *et al.*, 1989) and that phosphorylation of Y537 is required for binding of the ER to the ERE (Arnold and Norides, 1995; Arnold *et al.*, 1995b). Further *in vitro* studies demonstrated that c-Src is able to phosphorylate Y537 and that this phosphorylation is necessary for homodimerization of the ER and for binding of estradiol (Arnold *et al.*, 1995a, 1997). In agreement with these findings, Castoria *et al.* (1996) reported that a non-hormone-binding form of the ER found in mammary tumors can be converted to a hormone-binding form by *in vitro* phosphorylation with a calcium/calmodulin-regulated kinase, which is thought to be a c-Src family member. However, additional studies in which Y537 was mutated to various amino acids suggest that phosphorylation of Y537 per se is unnecessary for estradiol-mediated activation of the ER but may be important in ligand-independent (i.e., growth factor-mediated) activation (Weis *et al.*, 1996; Lazennec *et al.*, 1997).

Although c-Src is capable of phosphorylating the ER, the ER may also influence c-Src activity. Estradiol treatment has been shown to increase c-Src tyrosine phosphorylation and kinase activity in MCF7 breast cancer cells (Migliaccio *et al.*, 1993, 1996) and to stimulate kinase activity of c-Src and its related family member, c-Yes, in colon carcinoma cells (Di Domenico *et al.*, 1996).

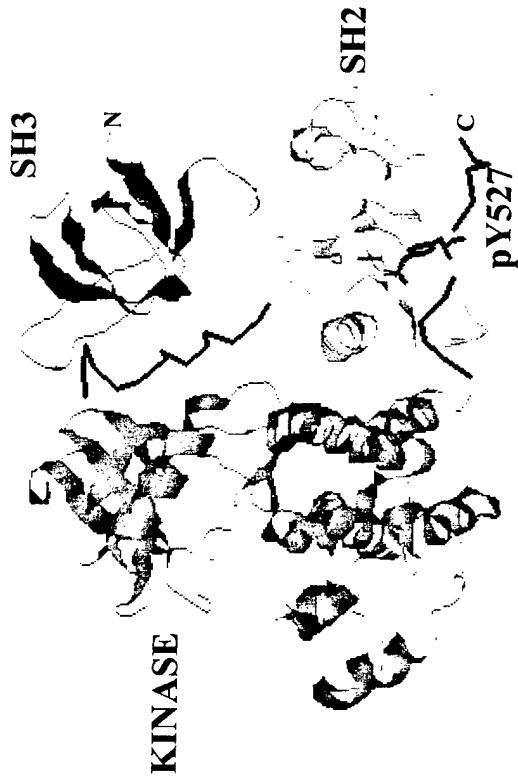

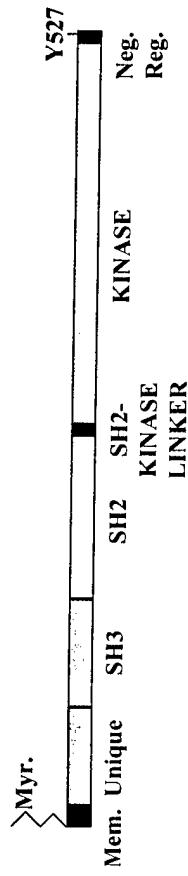

Ligand-independent down-regulation of the ER may also be mediated by

HER2 signaling pathways. Pietras *et al.* (1995) showed that overexpression of HER2 in MCF7 cells leads to estrogen-independent growth and ERE transcriptional activation. Furthermore, treatment of these cells with HRG, which stimulates HER2-dependent signaling via HER2/3 heterodimers, induces tyrosine phosphorylation and down-regulation of the ER. Other investigators have shown that HRG treatment inhibits the expression of ER in ER-positive breast cancer cells and can revert the estradiol-mediated decrease in HER2 expression (Grunt *et al.*, 1995). Taken together, these results suggest that in experimental cell systems, HER2 and the ER are expressed in a mutually exclusive manner. However, in human breast tumors, the situation is less clear, with some reports indicating an inverse correlation between HER2 and ER expression (Adnane *et al.*, 1989; Borg *et al.*, 1990) and others indicating no such correlation (Slamon *et al.*, 1989; Bacus *et al.*, 1996).

### III. c-Src AND c-Src FAMILY MEMBERS IN HUMAN CANCERS

#### A. c-Src Structure and Mechanisms of Regulation

c-Src is the cellular, nontransforming homolog of v-Src, the oncogene encoded by the chicken retrovirus, Rous sarcoma virus. c-Src is a 60-kDa tyrosine kinase that is composed of six domains: an N-terminal membrane-association domain, a "Unique" domain, SH3 and SH2 domains, a catalytic domain, and a negative regulatory domain (Fig. 2, see color plate). Although c-Src is cytosolic, it localizes to intracellular membranes, including the plasma membrane and membranes of endosomes and secretory vesicles within the cytosol (Parsons and Creutz, 1986; Kaplan *et al.*, 1992; Resh, 1994). It is tethered to these membranes by the combined action of an N-terminal, covalently linked myristate moiety, salt bridges between basic amino acids in the N terminus and phosphates of the lipid backbone, and noncovalent interactions with integral or associated membrane proteins (Resh, 1994). Membrane localization of c-Src is required for its ability to participate in growth factor receptor-mediated signaling in normal cells (Wilson *et al.*, 1989). The function of the Unique domain is not well-defined. However, based on the fact that it exhibits the greatest sequence divergence among family members of all the domains (Brown and Cooper, 1996), it is speculated to specify protein-protein interactions that are unique to individual Src family members. The SH3 and SH2 domains mediate the binding of c-Src with other signaling proteins through proline-rich or phosphoryrosine-containing regions on target proteins, respectively (Pawson and Schlessinger, 1993). The major regulatory region of the enzyme is a short domain at the extreme C terminus of

**Fig. 2** Structure of c-Src. c-Src is the prototype of a large family of cytoplasmic tyrosine kinases that associate with cellular membranes through lipid modifications at their N termini. As a linear molecule, the relationship between the various domains can be seen: an N-terminal membrane association domain that contains the site of myristylation, a Unique domain that exhibits the widest sequence divergence among family members of any of the domains, an Src-homology-3 (SH3) domain that binds poly(proline) motifs on target molecules, an SH2/kinase linker, the catalytic domain, and the negative regulatory domain that contains the predominant site of tyrosine phosphorylation on the inactive molecule (Y527 in chicken, Y531 in human). The three-dimensional orientation of the molecule, lacking the membrane-association and Unique domains, is depicted as a ribbon diagram. Reprinted with permission from Nature, Xu *et al.* (1997), and from Michael Eck (configured from the atomic coordinates provided on the Web). Copyright 1997 Macmillan Magazines Limited. The enzymatic activity of c-Src is regulated by the coordinated effects of target proteins binding to or covalent, post-translational modifications of the SH3, SH2, and negative regulatory domains on the catalytic domain, as described in the text.

the molecule, which harbors a Tyr residue that becomes phosphorylated (Y530 in human c-Src; Y527 in chicken c-Src) by a C-terminal Src kinase, CSK (Okada *et al.*, 1991). Phosphorylated Y527/Y530 (pY527) is capable of binding its own SH2 domain in a manner that inhibits kinase activity without physically blocking the catalytic site, as shown in Fig. 2 (Yamaguchi and Hendrickson, 1996; Sicheri *et al.*, 1997; Xu *et al.*, 1997).

Binding of tyrosine-phosphorylated cellular proteins to the SH2 domain is thought to destabilize the intramolecular pY527/SH2 domain interaction and induce a conformational change that results in enzymatic activation. Structural studies have revealed that the SH2 and SH3 domains collaborate in their binding of respective protein partners, thereby cooperatively influencing the activity of the enzyme (Eck *et al.*, 1994). Furthermore, crystallographic analysis has shown that sequences just N terminal to the catalytic domain (termed the SH2-kinase linker) comprises a loop structure that functions as a "pseudo" SH3 binding site (Yamaguchi and Hendrickson, 1996; Sicheri *et al.*, 1997; Xu *et al.*, 1997). Together, the intramolecular phosphotyrosine/SH2 and linker/SH3 interactions direct a conformation that pressses the linker against the backbone of the catalytic domain and renders the protein inactive. As with the SH2 domain, binding of signaling proteins to the SH3 domain is thought to release the constraints of the linker/SH3 interaction on the kinase domain, resulting in activation of catalytic activity. Mutation of Y527 to F or deletion of the C-terminal regulatory domain (as in v-Src) results in a constitutively active protein that phosphorylates target proteins in an unregulated fashion and induces cellular transformation and oncogenesis (Cartwright *et al.*, 1987; Kmiecik and Shalloway, 1987; Pownica-Worms *et al.*, 1987; Reynolds *et al.*, 1987). In normal cells, c-Src is nononcogenic or only weakly so, even when it is overexpressed (Shalloway *et al.*, 1984; Luttrell *et al.*, 1988). However, under certain conditions (growth factor stimulation or translocation; outlined below), the enzyme can become activated, either via dephosphorylation of pY527 or by binding of signaling proteins to the N-terminal half of the protein. Activation is most frequently a transient event, and c-Src, in contrast to v-Src, is thought to respond to negative control by rephosphorylation of Y527 or by the release of binding proteins and the resumption of intramolecular interactions. It has been the conjecture of many investigators that the transient nature of c-Src activation often prevents its detection. In fact, the possibility exists that little or no activation above basal levels is necessary for catalysis, if the substrate is properly positioned near the catalytic cleft. Thus, another "regulator" of c-Src activity may well be its intracellular localization and, at a finer level, its appropriate juxtaposition to substrate within a signaling complex. Identification of c-Src substrates and proteins that bind its SH2 and SH3 domains is now critical for further understanding of the role c-Src and its family members play in biological processes.

The majority of the studies leading to the above model have been conducted in animal tissue culture systems and are just now being applied to the study of c-Src in human tumors. In the following section evidence is presented for the involvement of c-Src in the genesis of human tumors, with particular emphasis on its putative role in colon, breast, lung, and myeloid tumors.

## B. Evidence for the Involvement of c-Src in Human Cancers

Like the RTKs, many lines of evidence are suggestive of a role for c-Src in the genesis and progression of multiple types of human cancer. This evidence is both genetic and biochemical in nature and has been generated by studies of cultured tumor cell lines and surgically generated tumor tissue. Together these studies have implicated c-Src as an etiological agent for the development of neuroblastomas, myeloproliferative disorders (including myeloid leukemia), and carcinomas of the colon, breast, lung, esophagus, skin, parotid, cervix, and gastric tissues. Interestingly, although alterations of c-Src have been described at both the gene and protein levels in various cancer tissues, the changes are quite variable and include both increases and decreases in gene copy number and in protein levels and specific enzyme activities. Taken at face value, these findings suggest multiple ways in which c-Src can contribute to the oncogenic process, both as a dominantly acting oncogenic protein and as a negatively acting tumor suppressor. However, the multitude of changes could also reflect fortuitous alterations that do not contribute to the ultimate malignant phenotype. There may also be technical reasons for the variability in the findings, such as the different probes used for genetic analysis and the different antibodies and cell extraction conditions used for biochemical analysis. It is clear that further work needs to be done to clarify these issues and attempts made to minimize technical problems. Of particular importance to future studies will be the development and characterization of good animal and tissue culture models to test the hypotheses derived from analyses of human tumor tissues, whereby the contribution of individual genes or proteins can be evaluated for their oncogenic potential against a normal cell background rather than against a heterogeneous background of unknown numbers and types of genetic alterations that occur in every human tumor.

### 1. GENETIC EVIDENCE

With the identification of the first protooncogenes came a plethora of studies examining the genomic content of multiple human tumors for deletions, amplifications, and diverse rearrangements in chromosomes containing pro-

tooncogenes. For the most part, these studies identified few if any gross changes in the c-Src gene, which maps to the q arm of chromosome 20. Furthermore, gene expression studies, employing a variety of techniques to measure steady-state levels and newly synthesized mRNA have also revealed few changes in c-Src-specific mRNA (Bishop, 1983; Slamon *et al.*, 1984). These findings led many investigators to conclude that c-Src played a minor (if any) role in the genesis of human tumors. Not until researchers began examining protein levels and specific enzyme activities did evidence for the involvement of c-Src begin to emerge.

However, there were a few exceptions to the general rule described above, and one in particular is noteworthy. Four groups have identified a deletion of 16–21 cM in the long arm of chromosome 20 [del(20q)] as a recurring, nonrandom abnormality in malignant myeloid disorders, including nonlymphocytic leukemia and polycythemia (Simpson, 1988; Roulston *et al.*, 1993; Hollings, 1994; Asimakopoulos *et al.*, 1994). This deletion maps between 20q11.2 and 20q13.3, a region that encodes the c-Src protooncogene (Hollings, 1994). The notion that deletion of a chromosomal region is significant for a tumor suppressor gene suggests that, if c-Src is a critical gene in this deletion, it behaves as a negative regulator of cell growth, not as a dominant oncogene, as is commonly believed. That c-Src may have some tumor suppressor-like characteristics in myeloid cells is supported by the finding of several groups (Barnekow and Gessler, 1986; Gee *et al.*, 1986) that c-Src expression levels increase during myeloid differentiation. If c-Src plays a critical role in promoting differentiation and maintaining the postmitotic state, then loss of such an activity might permit cells to once again acquire proliferative activity—the hallmark of a tumor suppressor.

### 2. BIOCHEMICAL EVIDENCE

By far the bulk of evidence supporting a role for c-Src in the development of human tumors comes from biochemical studies, wherein the levels of c-Src protein and tyrosine kinase activity have been examined in hundreds of human tumors and compared to normal tissue controls. As will be discussed in more detail below, in some tumor specimens, high enzymatic activity is accompanied by high protein level, yielding little or no change in specific activities, whereas in others, protein levels are only slightly or modestly elevated, and the specific activity of the enzyme is increased. In yet other examples, high protein levels are accompanied by low enzymatic activity. However, the overall conclusion is that in a very high percentage (>50% and approaching 100% in some studies) of human tumors of many different tissue types, c-Src activity is altered (usually elevated) and that this alteration occurs in early to middle stages of tumor progression and is maintained or increased throughout progression to metastasis.

These findings raise questions as to the mechanism of c-Src activation and the mechanisms by which protein levels are elevated (especially in light of the few instances of increases in c-Src-specific mRNA production). The consensus at the present time is that changes in c-Src specific activity in human tumors are due to posttranslational events and not to mutations of the gene. Using RNase protection and restriction fragment-length polymorphism assays to detect activating mutations of c-Src in a spectrum of human tumors, Wang *et al.* (1991) were unable to detect mutations at codons known to contribute to the oncogenicity of v-Src and c-Src (namely, codons 98, 381, 444, and 530 in the human c-Src sequence). These findings led the investigators to conclude that mutational activation is not the mechanism of enhancement of c-Src-specific kinase activity. On the other hand, DeSeau *et al.* (1987) described differential activation of c-Src in normal colon cells versus colonic tumor cells depending on the conditions of extract preparation, i.e., whether the lysis buffers contained the protein tyrosine phosphatase inhibitor, vanadate, and/or high concentrations of ionic and nonionic detergents. From these results, one could deduce that tyrosine phosphorylation of c-Src or other cellular proteins and protein/protein interactions play a role in regulating not only c-Src activity but also its stability and abundance. Indeed, structural studies on the c-Src molecule described above would support this notion. However, so as not to think that the issue is resolved, studies by Watanabe *et al.* (1995) indicate that in 18 cancer cell lines, elevated activities of c-Src and c-Yes (a Src-related family member) are accompanied by correspondingly elevated levels of C-terminal Src kinase, the protein that phosphorylates Y530 in human c-Src and negatively regulates c-Src kinase activity. These findings suggest that CSK may not have an antioncogenic role to play in tumor progression or that dephosphorylation of Y530 is not required for activation of c-Src.

Here the focus is on three different carcinomas—colon, breast, and lung—for which substantial amounts of data are accumulating to indicate a role for c-Src in their development. That these represent three of the four most common forms of cancer in adults (prostate cancer being the fourth) suggests that c-Src may be a more formidable player in tumorigenesis than had previously been appreciated.

### 3. COLON CANCER

Utilizing c-Src-specific antibodies and an immune complex-based tyrosine kinase assay, a number of investigators have reported that c-Src-specific tyrosine kinase activity (total activity relative to total c-Src protein in an immune complex) is elevated in colon cancer. In panels of colon cancers examined by Rosen *et al.* (1986), Bolen *et al.* (1987a,b), and Cartwright *et al.*

(1989), c-Src was found to exhibit elevated kinase activity, ranging from ~2- to 40-fold above that found in normal colon tissues or cultures of normal colon mucosal cells. In some cases this increase could be accounted for by increases in protein levels, but in other instances it could not, indicating an increase in specific kinase activity. These results suggest that either elevation in c-Src protein and/or activation of c-Src may contribute to the genesis of human colon tumors. Indeed, additional studies by Lundy *et al.* (1988) and Cartwright *et al.* (1990, 1994) demonstrated increased kinase activity in premalignant epithelia of ulcerative colitis and in early-stage colonic polyps compared to adjacent normal mucosa. In the latter study, activity was highest in malignant polyps and in >2-cm benign polyps that contained villous structure and severe dysplasia. Thus, c-Src activity is found to be elevated in early stages of colon cancer and this elevation is associated with those polyps that are at greatest risk for developing cancer. Talamonti *et al.* (1993) also demonstrated incremental increases in c-Src activity and protein level as the tumors progressed, with the greatest increases seen in metastatic lesions. Increases in specific kinase activity were also observed, with liver metastases exhibiting an average increase of 2.2-fold over normal mucosa, whereas extrahepatic metastases demonstrated an average 12.7-fold increase. These results support the idea that c-Src may play multiple roles in tumor progression.

A number of studies have been done to determine if c-Src indeed plays a causal role in tumor development. Herbimycin A, an inhibitor of Src family kinases, was shown to inhibit the growth in monolayer of seven colon tumor cell lines as compared to one cell line from normal colonic mucosa, CCL239 (Garcia *et al.*, 1991). In another study, blockage of the myristylation modification of Src family members in a panel of human colon adenocarcinoma tumor cell lines by N-fatty acyl glycinal compounds was shown to prevent localization of c-Src to the plasma membrane and to depress colony formation of these cell lines in soft agar and cell proliferation assays (Shoji *et al.*, 1990). Tumor necrosis factor (TNF- $\alpha$ -mediated growth inhibition of human colorectal carcinoma cell lines was accompanied by a reduction in the activity of c-Src (Novotny-Smith and Gallick, 1992). And last, using an antisense expression vector specific for c-Src, Staley *et al.* (1997) demonstrated that expression of c-Src antisense in HT29 human colon adenocarcinoma cells resulted in slower proliferation and slower growing tumors in nude mice as compared to the parental control. Together, these studies are consistent with a causative role for c-Src in colon cancer progression.

How could c-Src be functioning to promote progression of colonic tumors? Using an *in vitro* progression model based on the PC/AA premalignant colonic adenoma cell line, Brunton *et al.* (1997) demonstrated that in the conversion from adenoma to carcinoma, levels of both the EGF receptor and FAK protein increased, while the expression and activity of c-Src were

unaltered. However, EGF induced motility in the carcinoma cells, but not in the adenoma cells, and this increase was accompanied by an EGF-induced increase in c-Src kinase activity, relocation of c-Src to the cell periphery and phosphorylation of FAK. The authors interpret these findings to indicate that c-Src is not the driving force for tumor progression, but cooperates with other molecules (such as EGFR and FAK) in the process. Other investigators have observed that adhesion of HT29 human colon carcinoma cells to E-selectin results in a decrease in c-Src activity (Soltesz *et al.*, 1997), suggesting that, on release from substratum restrictions, c-Src activity is restored or elevated. In a related study, Empereur *et al.* (1997) generated evidence for cooperativity between c-Src and HGF/SF in developing invasive properties of the PC/AA cell line. Specifically, introduction of activated c-Src or polyclonal middle-T antigen (which requires c-Src for oncogenic activity) into the adenoma PC/AA cell line induced conversion of the adenoma to carcinoma, overexpression of the HGF receptor, and an invasive capacity in the presence of HGF. Thus, current evidence suggests that one mechanism by which c-Src promotes colonic tumor progression is by cooperating with components of the cell adhesion/motility machinery. Similar conclusions were reached by Mao *et al.* (1997), who demonstrated activation of c-Src in response to EGF or HGF treatment of human colon cancer cells with high metastatic potential.

#### 4. BREAST CANCER

As with colon cancer, a number of early investigations reported elevated c-Src activity in human breast cancers (Jacobs and Rubsamen, 1983; Rosen *et al.*, 1986; Lehrer *et al.*, 1989). In several reports the elevation in activity was not accompanied by elevated levels of c-Src protein, suggesting an activation of the protein. However, Koster *et al.* (1991), using a screening method based on *in vitro* synthesis of cDNA copied from total cellular RNA of tumor tissue, found that 25–30% of the analyzed tumors showed significant elevations in expression of several protooncogenes, including c-Src. Using immune complex kinase assays, immunoblotting, and immunohistochemical approaches, Verbeek *et al.* (1996) and Biscardi *et al.* (1998a) demonstrated that increases in c-Src kinase activity are almost invariably accompanied by increases in c-Src protein levels and little if any change in specific kinase activity. Interestingly, the immunohistochemical studies of Verbeek *et al.* (1996) showed that in malignant cells, the majority of c-Src

occur in breast tumor cells; rather, elevations in protein levels appear to be the major cause of the increases in c-Src kinase activity. In a recent study involving 72 breast cell lines and tumor biopsies, tyrosine kinase activity was found to be elevated in 100% of the samples, as compared to normal tissue controls, and c-Src tyrosine kinase accounted for 70% of the total cytosolic activity (Ottenhoff-Kalff *et al.*, 1992). The same group performing that study had previously found that the level of cytosolic protein tyrosine kinase activity parallels the malignancy in breast tumors (Hennipman *et al.*, 1989) and that the majority of this activity is precipitated by anti-c-Src antibodies. These results provide compelling correlative evidence that c-Src plays a key role in the development of breast cancer. In agreement with this conclusion, Lehrer *et al.* (1989) and Koster *et al.* (1991) also note that elevated c-Src kinase activity is most frequently found in tumors that are progesterone receptor negative. Because loss of progesterone receptor is a histochemical marker for later stage tumors, c-Src activity appears to increase as the tumor progresses in severity.

To directly assess the effect of mammary gland-specific expression of c-Src, Webster *et al.* (1995) established transgenic mice that carried a constitutively activated form of c-Src under the transcriptional control of the murine mammary tumor virus long terminal repeat. Female transgenic mice exhibited a lactation defect and frequently developed mammary epithelial hyperplasias, which occasionally progressed to frank neoplasias. The authors interpret these results to mean that expression of activated c-Src in the mammary gland is not sufficient for induction of mammary tumors—that some other event must take place for frank neoplasias to occur. That c-Src can play more than a bystander role in tumor development, however, was demonstrated by the experiments of Guy *et al.*, (1994), wherein mice transgenic for the polyoma virus middle-T antigen under the control of the murine mammary tumor virus long terminal repeat developed tumors when in a genetic background positive for c-Src, but not when in a background null for c-Src. Similar results were obtained by Amini *et al.* (1986a), who used c-Src antisense expression vectors to demonstrate that c-Src is required for transformation of rat FR3T3 cells by polyoma middle-T antigen in tissue culture. Together, these studies indicate that c-Src is necessary but not sufficient for tumor development in the mammary gland.

#### 5. LUNG CANCER

Lung cancer is the leading cause of cancer death in the United States. Small cell lung cancer (SCLC) accounts for 20–25% of all bronchogenic carcinomas and is associated with the poorest 5-year survival of all histologic types. c-Src expression was found to be elevated in 60% of all lung cancers (Mazurenko *et al.*, 1991b), when biopsy material of tumors, metastases, and

“normal” surrounding tissues from patients with different histological types of stomach and lung cancer, melanoma, and other malignancies were analyzed by immunoblotting and immunohistochemistry. A breakdown of the lung histologic types exhibiting increased c-Src expression revealed that c-Src protein was elevated in SCLC and atypical carcinoid tumors, as well as in non-small-cell tumors, such as adenocarcinoma, bronchoalveolar, and squamous cell lung cancer (Mazurenko *et al.*, 1991a). In these studies no analysis of c-Src kinase activity was reported. Somewhat contrasting results were reported by authors of a study in which 60 human cell lines used by the National Cancer Institute for the random screening of potential anticancer drugs were analyzed for c-Src kinase activity. In this study SCLC-derived cell lines had a low activity, whereas non-small-cell lung tumors exhibited activity that was greater than that observed in colon cancer cells, which are considered to have high c-Src activity (Budde *et al.*, 1994). The findings from these studies are strongly supportive of other investigations, concluding that c-Src is frequently overexpressed in SCLC, and other types of lung cancer (Cook *et al.*, 1993).

## 6. OTHER CANCERS

Many other tumor types exhibit elevations in c-Src kinase activity or protein/mRNA levels, including neuroblastomas (Bjelfman *et al.*, 1990) and carcinomas of the esophagus (Jankowski *et al.*, 1992; Kumble *et al.*, 1997), gastric tract (Takekura *et al.*, 1990), parotid gland (Bu *et al.*, 1996), ovary (Budde *et al.*, 1994), and skin (Kim *et al.*, 1991). With regard to skin cancers, a study carried out in a mouse model of epidermal tumor promotion described activation of erbB2 and c-Src in phorbol ester-treated mouse skin as a possible mechanism by which phorbol esters promote skin tumors in mice. Activation of erbB2 and c-Src kinase is also observed in the epidermis of TGF $\alpha$  transgenic mice, where expression of human TGF $\alpha$  was targeted to basal keratinocytes (Xian *et al.*, 1997). In cervical cancer, evidence is beginning to emerge for cis activation of cellular protooncogenes (including c-Src by integration of human papillomavirus DNA into the genome of cervical epidermal cells (Durst *et al.*, 1987). In tissue culture studies using primary hamster embryo cells, infection with other DNA tumor viruses, such as SV40, adenovirus, or bovine papillomavirus, also results in increases in the specific activity of c-Src (Amini *et al.*, 1986b).

Sudol *et al.*, 1993; Brown and Cooper, 1996). All members have the same overall structure and minimally contain Unique, SH3, SH2, and kinase domains. The greatest sequence divergence occurs in the Unique domain, thus its name. Not all members are linked to lipids at the N terminus, nor are all negatively regulated by a C-terminal domain that includes the Tyr-530 homolog of human c-Src. c-Fgr, Lck, Hck, and Blk are expressed predominantly in cells of hematopoietic lineage, whereas c-Src, c-Yes, Fyn, Lyn, and Yrk are more ubiquitous. All members have been implicated in various signal transduction pathways, and with the mounting evidence for involvement of c-Src in the genesis of multiple human cancers, the question arises as to whether close relatives of c-Src may also be implicated in these diseases. If so, there are other questions that warrant investigation: Is more than one family member involved in the genesis of the same tumor type? Do c-Src family members fulfill overlapping or unique functions in promoting tumor formation and progression? Are there members of this family that are expressed exclusively in tumors as compared to normal tissue? A review of the literature reveals a paucity of information with regard to any of these issues. It is not clear whether this paucity reflects the unavailability of useful and appropriate reagents to investigate the questions, or whether studies have been conducted and few have uncovered evidence for c-Src family member involvement. Although the following description is not meant to be comprehensive, it does suggest that family members in addition to c-Src may be involved in the genesis of human and certain animal tumors.

## 1. GENETIC EVIDENCE

In humans, sequences related to the human c-Yes gene were found to be amplified in a single primary gastric cancer out of 22 cases that were examined (Seki *et al.*, 1985). The sequences were amplified four- to fivefold, but normal stomach tissue adjacent to the tumor tissue in the same patient showed no amplification. In the dog, a protooncogene related to the human c-Yes gene was detected as restriction fragment-length polymorphisms (RFLPs) in a Southern blot analysis of genomic DNA from six canine primary mammary tumors in a screen employing seven protooncogene probes. These RFLPs were 0.1 to 1.0 kb shorter than the normal gene, suggesting the occurrence of chromosomal rearrangements and possible deregulation of gene expression, leading to tumorigenesis (Miyoshi *et al.*, 1991). Melanoma formation in the fish *Xiphophorus* is a genetic model for the function of tyrosine kinases in tumor development. In malignant melanomas from these fish, elevated levels of c-Yes and Fyn activity have been detected as compared to normal tissue (Hannig *et al.*, 1991). Fyn has also been found to coprecipitate with the *Xiphophorus* melanoma receptor kinase (Xmrk), the molecule

## C. c-Src Family Members and Human Cancers

c-Src is the prototype for a family of nonreceptor protein tyrosine kinases, for which novel members are regularly being identified. Current members

that is responsible for the formation of hereditary malignant melanoma in this lower vertebrate (Wellbrook *et al.*, 1995). These results suggest that Xmrk may function at least in part through Fyn in melanoma formation.

## D. Nonreceptor Tyrosine Kinases Related to c-Src Family Members and Human Cancers

**2. BIOCHEMICAL EVIDENCE**

In studies similar to those conducted for c-Src, evidence for the involvement of other c-Src family members in the etiology of human cancers is emerging, but at a much slower pace than that for c-Src. Elevated c-Yes tyrosine kinase activity has been detected in premalignant lesions of the colon that are at greatest risk for developing cancer (Peña *et al.*, 1995). In this study, the activity of c-Yes in such adenomas was 12- to 14-fold greater than activity in adjacent normal mucosa. Similar results were obtained when mRNA levels of nine protooncogenes in colonic tissue from patients with inflammatory bowel disease (IBD) were measured. The steady-state level of c-Yes-encoded mRNA was considerably higher in IBD patients resected for colon cancer than in patients resected for active chronic IBD or in controls (Alexander *et al.*, 1996). These results suggest that expression of this gene may be a marker for development of colon cancer in IBD. Finally, in rodents, the action of the transforming proteins of mouse and hamster polyomaviruses (middle-T antigens) is mediated in part through c-Src family kinases, with preferential action of hamster T antigen for Fyn (Brizuela *et al.*, 1995).

c-Src family members have also been implicated in the genesis of diseases involving Epstein-Barr Virus (EBV), such as Burkitt's lymphoma, Hodgkin's disease, and nasopharyngeal cancer. All of these diseases involve abnormal proliferation of B cells. EBV encodes two transformation-associated proteins, LMP1 and LMP2, that are integral membrane proteins. LMP2 mRNA is the only EBV-specific message detected in B lymphocytes from individuals harboring EBV latent infections. LMP2 protein also associates with c-Src family tyrosine kinases, LMP1, and other unidentified proteins, suggesting that the association of these two EBV-encoded membrane proteins could create a macromolecular complex mediating constitutive B lymphocyte activation through normal cell signal transduction pathways (Longnecker, 1994). In human malignant melanoma and other cancers, aberrant expression of basic fibroblast growth factor (bFGF) causes constitutive autocrine activation of its cognate receptor and autonomous growth of tumor cells in culture (see above). Expression of a dominant-negative mutant of the FGF receptor (lacking the kinase domain) was found to suppress tumor formation in nude mice and markedly reduce c-Src family kinase activity in melanoma cells (Yayon *et al.*, 1997). Together these studies suggest that c-Src family kinases play an important role in maintenance and/or progression of malignant melanoma.

Several new nonreceptor tyrosine kinases have been isolated from human breast cancer cells. A cDNA encoding a 54-kDa phosphoprotein, called Rak, was cloned from human breast cancer cells (Cancer *et al.*, 1994). This protein shares 51% identity with c-Src and contains SH3, SH2, kinase, and negative regulatory domains. However, it has some properties that are distinct from c-Src, such as its predominant expression in epithelial cells, its lack of a myristylation site, and its almost exclusive localization to the nucleus. However, like c-Src, Rak is overexpressed in subsets of primary human epithelial tumors, suggesting that it may play a role in development of human cancer. Another protein, named Brk (breast tumor kinase), appears to be expressed exclusively in breast tumor tissue as opposed to normal mammary epithelium (Barker *et al.*, 1997). Approximately two-thirds of breast tumors express appreciable levels, and 27% of these overexpress Brk 5- to 40-fold or more. When overexpressed in fibroblasts or mammary epithelial cells, Brk sensitizes cells to the action of EGF and also induces a partial transformed phenotype (Kamalati *et al.*, 1996). These findings suggest that Brk is a functionally important factor in the evolution of breast cancer.

## V. MECHANISMS OF c-Src ACTION

### A. Evidence for Involvement of c-Src in Signaling through Receptor Tyrosine Kinases

The elevated levels of c-Src expression and/or activation in a wide spectrum of human tumors suggest that c-Src is contributing in some way to the neoplastic phenotype. That c-Src is overexpressed in many of the same tumors in which specific RTKs are also often overexpressed suggests that the two classes of tyrosine kinases may functionally interact to promote tumorigenesis. Many of the RTKs are oncogenic when overexpressed or appropriately expressed, as described above. The question that follows is whether c-Src is required for the oncogenic capabilities of overexpressed RTKs, or whether c-Src enhances or contributes to RTK-mediated oncogenesis by any means. This latter question was in part addressed when it was shown that cooverexpression of c-Src with HER1 in a mouse fibroblast model resulted in synergistic increases in tumor volume, as compared to tumors developed by cells overexpressing only one of the pair of kinases (Maa *et al.*, 1995). These results provided direct evidence for the enhancing effect of c-Src on receptor-transforming ability, and suggested that a similar synergism

may be occurring in human tumors that coexpress c-Src and the EGFR or other RTKs. Targets of c-Src action can be inferred from an analysis of its known intracellular substrates, which, besides the cell surface receptors, are almost exclusively proteins that regulate actin cytoskeleton dynamics. Thus, c-Src appears to have the capability of affecting both mitogenic growth pathways and morphogenic pathways that influence cell/matrix and cell/cell interactions, motility, invasiveness, and metastasis. Here the focus is on studies that are beginning to reveal the molecular interactions between c-Src and its substrates (as they relate to malignancy) and the effects phosphorylation by c-Src have on their functions. It is becoming clear that c-Src is an obligate partner in mediating mitogenic signaling of at least two RTKs, specifically the PDGFR and EGF receptors, and that in the case of EGFR, c-Src mediates tumorigenic signaling as well. This new information, in turn, can be used to design novel diagnostics and therapeutics to interdict the symbiotic relationship between c-Src and the RTKs.

A number of different growth factor receptors that have been shown to associate with or activate c-Src or Src family members were enumerated in Section I. These included receptors for PDGF, CSF-1, HGF/SF, and EGF, as well as HER2. With the exception of the PDGFR and EGFR, little is known about the role of c-Src in signaling through these receptors, other than the fact that c-Src either associates with the receptor or is activated following specific ligand stimulation. Therefore, we focus our discussion on c-Src interactions with the PDGF and EGF receptors. The data implicating c-Src in PDGF-dependent signaling will be briefly summarized, this being the subject of several other reviews. The bulk of our attention will then be focused on the mechanism of interaction between c-Src and EGFR family members.

In our laboratory, initial attempts to detect *in vitro* peptide binding studies (Alonso *et al.*, 1995) suggest that Y579 and Y581 directly mediate binding of Src family members to the PDGFR. Interaction of c-Src with the PDGFR appears to have consequences for both c-Src and the PDGFR. Hansen *et al.* (1996) have shown that Y934 in the kinase domain of the PDGFR is phosphorylated by c-Src both *in vitro* and *in vivo*. Expression of a receptor harboring a phenylalanine substitution at residue 934 in intact cells results in a decreased mitogenic signal and an increase in chemotaxis and motility, along with enhanced PLC $\gamma$  tyrosine phosphorylation. These data suggest that phosphorylation of Y934 by c-Src positively regulates mitogenesis, while negatively regulating cell motility, possibly via a PLC $\gamma$ -mediated pathway. Activation of c-Src by PDGF is also accompanied by the appearance of novel phosphorylations on c-Src, including two serine phosphorylations, S12 and an unidentified S residue (Gould and Hunter, 1988), and one tyrosine phosphorylation, Y138 (Broome and Hunter, 1997). Y138 is located in the SH3 domain of c-Src, and phosphorylation of this residue diminishes the ability of peptide ligands to bind the SH3 domain *in vitro*. Mutation of Y138 or Y133 to phenylalanine or complete deletion of the SH3 domain reduces the mitogenic effect of PDGF (Er et al., 1996; Broome and Hunter, 1996). The hypothesis that Src family members are required for PDGF-dependent signaling is supported by the inhibitory effects of kinase-inactive c-Src or an antibody specific for the C-terminal domain of Src family members on PDGF-induced BrdU incorporation into newly synthesized DNA (Twamley-Stein *et al.*, 1993).

## 2. ROLE OF c-Src IN SIGNALING FROM EGFR

### 1. ROLE FOR c-Src IN SIGNALING FROM THE PDGFR

The first evidence that c-Src participates in PDGFR signaling came from the work of Ralston and Bishop (1985), who first observed that c-Src becomes activated on PDGF stimulation. Kypta *et al.* (1990) later demonstrated that c-Fyn and c-Yes are also activated in a PDGF-dependent manner. Activation of c-Src was shown to be accompanied by a translocation of c-Src from the plasma membrane to the cytosol (Walker *et al.*, 1993), a process that may be linked to internalization of the receptor. PDGF stimulation was also shown to stimulate transient association of Src family members with the PDGFR (Kypta *et al.*, 1990). Association between Src family members and the receptor is believed to involve phosphorylation–SH2 interactions, because the SH2 domain of c-Fyn is required for binding to the receptor *in vitro* (Twamley *et al.*, 1992) and mutation to phenylalanine of Y579 and Y581 in the juxtamembrane region of the receptor results in a decrease in both PDGF-induced c-Src activation and binding to the receptor in

*in vitro* peptide binding studies (Mori *et al.*, 1993). These data and results from *in vitro* peptide binding studies (Alonso *et al.*, 1995) suggest that Y579 and Y581 directly mediate binding of Src family members to the PDGFR.

Interaction of c-Src with the PDGFR appears to have consequences for both c-Src and the PDGFR. Hansen *et al.* (1996) have shown that Y934 in the kinase domain of the PDGFR is phosphorylated by c-Src both *in vitro* and *in vivo*. Expression of a receptor harboring a phenylalanine substitution at residue 934 in intact cells results in a decreased mitogenic signal and an increase in chemotaxis and motility, along with enhanced PLC $\gamma$  tyrosine phosphorylation. These data suggest that phosphorylation of Y934 by c-Src positively regulates mitogenesis, while negatively regulating cell motility, possibly via a PLC $\gamma$ -mediated pathway. Activation of c-Src by PDGF is also accompanied by the appearance of novel phosphorylations on c-Src, including two serine phosphorylations, S12 and an unidentified S residue (Gould and Hunter, 1988), and one tyrosine phosphorylation, Y138 (Broome and Hunter, 1997). Y138 is located in the SH3 domain of c-Src, and phosphorylation of this residue diminishes the ability of peptide ligands to bind the SH3 domain *in vitro*. Mutation of Y138 or Y133 to phenylalanine or complete deletion of the SH3 domain reduces the mitogenic effect of PDGF (Er et al., 1996; Broome and Hunter, 1996). The hypothesis that Src family members are required for PDGF-dependent signaling is supported by the inhibitory effects of kinase-inactive c-Src or an antibody specific for the C-terminal domain of Src family members on PDGF-induced BrdU incorporation into newly synthesized DNA (Twamley-Stein *et al.*, 1993).

In our laboratory, initial attempts to detect EGF-induced alterations in c-Src kinase activity or physical association between c-Src and the EGFR in a panel of nontransformed avian and rodent cell lines were negative, or yielded inconsistent results (Luttrell *et al.*, 1988). Therefore, a direct test of the involvement of c-Src was undertaken, in which wild-type (wt) and mutant variants of c-Src were overexpressed in C3H10T1/2 mouse fibroblasts, and the effect of overexpression of these variants on EGF-induced [ $^3$ H]thymidine incorporation was examined. Overexpression of wt c-Src resulted in a two- to fivefold increase in [ $^3$ H]thymidine incorporation above Neo-only controls (Luttrell *et al.*, 1988), whereas overexpression of c-Src harboring inactivating mutations in the kinase, SH2, or myristylation domains resulted not only in a reduction in the enhanced effect of overexpressed wt c-Src but also in a dominant negative effect on endogenous, EGF-induced DNA synthesis (Wilson *et al.*, 1989). These results indicated not only that c-Src is required for mitogenesis stimulated by EGF, but also that c-Src kinase activity, an intact SH2 domain, and membrane association are

necessary to fulfill the role of c-Src in the process. These findings were corroborated by studies in NIH3T3 cells, in which a decrease in EGF-induced BrdU incorporation was observed on microinjection of antibodies to c-Src family members or introduction of a kinase-inactive c-Src cDNA into cells (Roche *et al.*, 1995).

c-Src was also shown to affect EGF-induced tumorigenesis (Maa *et al.*, 1995). In C3H10T1/2 cells, coexpression of c-Src and the HER1 results in synergistic increases in proliferation, colony formation in soft agar, and tumorigenicity in nude mice, as compared to cells overexpressing c-Src or HER1 alone. Furthermore, under conditions of receptor and c-Src overexpression, an EGF-inducible complex between the proteins can be detected. Enhanced tumor growth correlates with the ability of c-Src to associate stably with the receptor, the appearance of two novel tyrosine phosphorylation sites on the receptor, and enhanced phosphorylation of the receptor substrates, Shc and PLC $\gamma$ . These findings suggest that c-Src association with and phosphorylation of the receptor results in hyperactivation of the receptor and enhanced mitogenic signaling to downstream effectors. Subsequent investigations have revealed that the kinase activity of c-Src is required for the biological synergy between c-Src and overexpressed HER1 (Tice *et al.*, 1998). Kinase-defective c-Src, when expressed in a cell line overexpressing HER1, acts in a dominant negative fashion to inhibit EGF-dependent colony formation in soft agar and tumorigenicity in nude mice. The effects of both wt and kinase-defective c-Src are very striking, with the single wt c-Src or HER1 overexpressors forming barely detectable tumors in nude mice ( $<300 \text{ mm}^3$ ) and the c-Src/HER1 double overexpressor forming large tumors ( $\sim 1600 \text{ mm}^3$ ). In contrast, the HER1/kinase-defective c-Src overexpressors form no palpable tumors. Thus, the extent of tumor inhibition by kinase-defective c-Src is complete in this model system, and the results suggest that the catalytic activity of c-Src may be a fruitful target for human tumor therapy. Interestingly, expression of c-Src variants that bear mutations in either the SH2 or myristylation domains augments, rather than inhibits, tumor formation of cells overexpressing the receptor (D. A. Tice, unpublished). These results are in surprising contrast to those observed when the same c-Src variants are expressed in cells containing normal levels of EGFR (see above and Wilson *et al.*, 1989). The mechanism by which tumor growth is enhanced by these variants is not known.

The mechanism of synergy between wt c-Src and HER1 is beginning to be elucidated. Several groups have now demonstrated an EGF-dependent complex formation between c-Src and the HER1 (Luttrell *et al.*, 1994; Maa *et al.*, 1995; Stover *et al.*, 1995) and an EGF-induced activation of c-Src-specific kinase activity (Osherov and Levitzki, 1994; Oude Weernink *et al.*, 1994). In all instances, these events are seen in cells overexpressing one or both partners, suggesting that the interaction is either transient or low affinity.

In addition, there is evidence for phosphorylation of HER1 by c-Src on EGF stimulation. In the C3H10T1/2 murine fibroblasts, two sites of tyrosine phosphorylation on c-Src-associated HER1 have been identified both *in vitro* and *in vivo* as Y845 and Y1101 (Biscardi *et al.*, 1998b). Y845 has also been identified as a c-Src-specific phosphorylation site in A431 cells (Sato *et al.*, 1995) and in MDA-MB-468 breast cancer cells (Biscardi *et al.*, 1998b), whereas two other nonautophosphorylation sites, Y891 and Y920, were identified on the receptor from MCF7 cells (Stover *et al.*, 1995). Tice *et al.* (1998) have shown in 10T1/2 cells that Y845 is the only phosphorylation that is completely dependent on c-Src kinase activity, implicating a direct phosphorylation of the receptor by c-Src at this site, and suggesting that phosphorylation of other c-Src-dependent sites may involve a third component.

Y845 is located in the activation loop of the kinase domain and is highly conserved among all tyrosine kinases, receptor and nonreceptor alike. Its homolog in c-Src is Y416. Phosphorylation at the homologous site in other kinases is required for full enzymatic activation, through ATP and substrate accessibility (Ellis *et al.*, 1986; Fanti *et al.*, 1989; Knighton *et al.*, 1991; van der Geer and Hunter, 1991; Longati *et al.*, 1994; Kato *et al.*, 1994; Russo *et al.*, 1996; Yamaguchi and Hendrickson, 1996; Mohammadi *et al.*, 1996; Hubbard, 1997). In 10T1/2 cells the presence of this phosphorylation on the HER1 correlates with an increase in tyrosine phosphorylation of receptor substrates Shc and PLC $\gamma$ , and enhanced growth and tumor formation (Maa *et al.*, 1995), consistent with hyperactivation of the receptor. Conversely, the absence of this phosphorylation (in 10T1/2 cells overexpressing receptor and kinase-defective c-Src) correlates with reduced growth and tumor formation. Thus, phosphorylation of Y845 appears to be required for the oncogenic capabilities of the receptor. Interestingly, in all other kinases but HER1, the Y845 homolog is an autophosphorylation site. That Y845 has not been identified in the HER1 may be due to the high lability of the phosphotyrosine. Interestingly, expression of c-Src variants that bear mutations in either the SH2 or myristylation domains augments, rather than inhibits, tumor formation of cells overexpressing the receptor (D. A. Tice, unpublished). These results are in surprising contrast to those observed when the same c-Src variants are expressed in cells containing normal levels of EGFR (see above and Wilson *et al.*, 1989). The mechanism by which tumor growth is enhanced by these variants is not known.

The mechanism of synergy between wt c-Src and HER1 is beginning to be elucidated. Several groups have now demonstrated an EGF-dependent complex formation between c-Src and the HER1 (Luttrell *et al.*, 1994; Maa *et al.*, 1995; Stover *et al.*, 1995) and an EGF-induced activation of c-Src-specific kinase activity (Osherov and Levitzki, 1994; Oude Weernink *et al.*, 1994). In all instances, these events are seen in cells overexpressing one or both partners, suggesting that the interaction is either transient or low affinity.

#### EGF Receptor Internalization

Based on evidence that implicates the actin cytoskeleton as critical for GFR internalization (Lamaze *et al.*, 1997), and the involvement of c-Src and c-Src substrates in actin dynamics, as well as the localization of c-Src to

membranes of intracellular vesicles (Parsons and Creutz, 1986; Kaplan *et al.*, 1994; Henke *et al.*, 1996; Li *et al.*, 1996a,b). Caveolin normally acts as a scaffolding protein to bind inactive signaling molecules, such as Gα subunits, Ras, EGFR, and c-Src (Sargiacomo *et al.*, 1993; Lisan-*et al.*, 1994; Chang *et al.*, 1994; Li *et al.*, 1995; Couet *et al.*, 1997). It has also been shown that caveolin expression is down-modulated in cells trans-*to this hypothesis, however, it was found in studies of 10T1/2 cells that formed by various oncogenes (Koleske *et al.*, 1995), and that reexpression c-Src overexpression enhances rather than inhibits receptor internalization and increasing steady-state pools of internalized, activated receptors (Ware *et al.*, 1997). Receptor recycling rates are not altered. The kinase activity of c-Src is required for the increase, because overexpression of kinase-deficient c-Src exhibits basal or slightly reduced internalization rates.*

*How might the increased internalization contribute to the enhanced cell proliferation and tumorigenic potential seen in cells overexpressing wt c-Src? Recent evidence indicates that receptor/SHC/GRB2/SOS complexes are present in endosomes (DiGuglielmo *et al.*, 1994), suggesting that EGFR/EGFR complexes continue to signal in the endosomal compartment (Baass *et al.*, 1995; Bevan *et al.*, 1996). Because c-Src overexpression increases the steady-state pool of internalized, activated receptors, c-Src may enhance mitogenic signaling by promoting the frequency of interactions between receptor complexes in the endosomes and Ras at the plasma membrane.*

*Although the mechanism by which c-Src affects EGFR internalization is unknown, several possibilities are plausible. First, c-Src may increase the rate of association of the EGFR with components of the endocytic pathway, such as the adaptins (Sorkin and Carpenter, 1993), or Grb2 (Wang and Moran, 1996), which are thought to recruit activated receptors into clathrin-coated pits. Interestingly, Grb2 associates with dynamin (Gout *et al.*, 1993), a GTPase that is critical for the formation and release of the endosome from the plasma membrane. The c-Src SH3 domain is also reported to activate the GTPase activity of dynamin *in vitro* (Herskovits *et al.*, 1993). These considerations suggest that as a second mechanism, overexpression of c-Src could result in the activation or recruitment of a pool of dynamin larger than that in cells expressing normal levels of c-Src.*

*A third mechanism by which c-Src may affect EGFR internalization is through processes that do not involve clathrin-coated pits, such as through caveolae. Caveolae are small invaginations of the plasma membrane that have been implicated in the transcytosis of macromolecules across capillary endothelial cells, the uptake of small molecules, interactions with actin-based cytoskeleton, and the compartmentalization of certain signaling molecules, including G-protein-coupled receptors, H-Ras and Ras-related GTPases, and members of the Src family of tyrosine kinases (Li *et al.*, 1996a,b). Caveolae act as to whether c-Src acts as a co-transducer to tumorigenic signals are enriched for a specific protein, caveolin, which is a substrate for v-Src (Li *et al.*, 1994) and has also been shown to copurify with c-Src in normal ER2 can be precipitated by the GSTc-SrcSH2 fusion protein from a hu-*

#### Evidence for the HER1/c-Src Synergy Model in Human Breast Cancer

Simultaneous overexpression or activation of HER1 and c-Src in a significant portion of human breast tumors suggests that the two molecules might functionally interact in human tumors as they do in the 10T1/2 murine fibroblast model. This question was examined by Biscardi *et al.* (1998a,b), who analyzed a panel of 14 breast tumor cell lines and over 20 tissue samples of association between c-Src overexpression, association between c-Src and HER1, phosphorylation of Y845 and Y1101 on the receptor in complex pits. Increases in Shc phosphorylation, MAP kinase activation, and tumor formation in nude mice. A direct correlation was found between the expression levels of c-Src and HER1 and the ability to detect interactions between the two kinases, the presence of the novel phosphorylation of downstream substrates, and tumor formation. Although not direct proof, results from these studies are consistent with those in the 10T1/2 model and suggest that c-Src and HER1 can functionally synergize to promote tumor progression when overexpressed in human tumors.

#### c-Src/HER2/neu INTERACTIONS

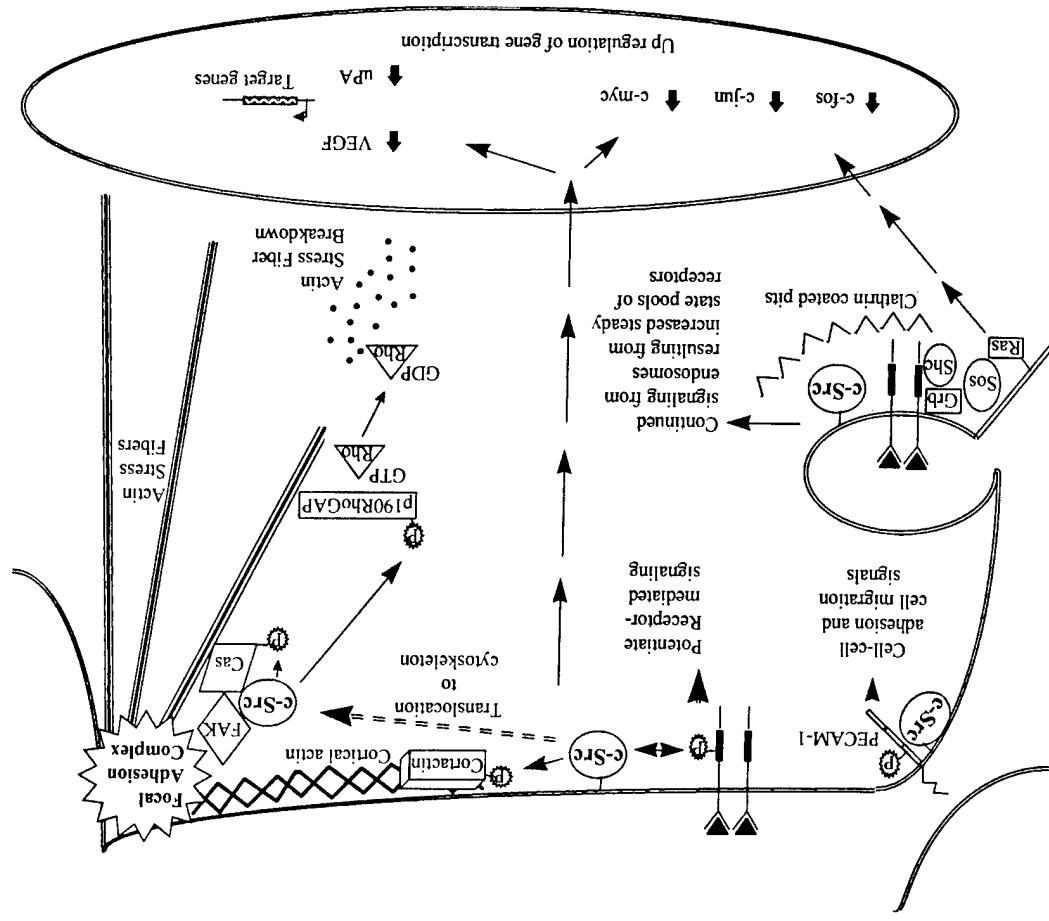

Because HER2/neu is so abundantly and frequently overexpressed in human tumors (particularly in breast cancers) and is oncogenic when overexpressed in cultured fibroblasts (DilFiore *et al.*, 1987b), an important question is as to whether c-Src acts as a co-transducer to tumorigenic signals that does through HER1. Luttrell *et al.* (1994) showed that the GSTc-SrcSH2 fusion protein from a hu-

man breast cancer cell extract, suggesting that stable complexes may also form between c-Src and HER2 *in vivo*. c-Src association with and activation by HER2 was also shown in mammary tumors from HER2 transgenic mice (Muthuswamy *et al.*, 1994; Muthuswamy and Muller, 1995). Moreover, in coimmunoprecipitation studies our laboratory has detected c-Src in association with HER2 in 3 of 14 human breast tumor cell lines and in 3 of 13 tumor tissues (Belsches and Parsons, 1998). Cell lines exhibiting this complex respond to HRG mitogenically and tumorigenically, as measured by cell growth assays and colony formation in soft agar, in contrast to those cell lines that express HER2 but form no complex with c-Src. Interestingly, in contrast to the HER1, overexpression of neither HER2 nor c-Src is a prerequisite for detecting association between the two proteins. These data suggest that c-Src may potentiate HER2-dependent tumorigenicity through mechanisms similar as well as dissimilar to those described for HER1.

## B. Targets of c-Src

### 1. TARGETS WHOSE EXPRESSION LEVELS ARE AFFECTED BY c-Src

The preceding discussion provides compelling evidence that RTKs can be direct targets of c-Src. Phosphorylation of specific sites by c-Src appears to regulate the shift from motility to mitogenesis in the case of the PDGFR (Hansen *et al.*, 1996) and the entrance into S phase of the cell cycle in the case of the EGFR (Fig. 3) (Tice *et al.*, 1998). Is c-Src capable of contributing to the malignant phenotype in ways other than through direct regulation of growth factor receptors? One alternative is the ability of c-Src to regulate gene transcription. Barone and Courtneidge (1995) showed that Myc was required to overcome a block of PDGF-induced DNA synthesis by kinase-deficient c-Src, suggesting that Src kinases control the transcriptional activation of Myc, which in turn can induce a program of gene transcription that

**Fig. 3** Targets of c-Src and their potential roles in transformation. c-Src associates with and phosphorylates the ligand-activated EGF receptor, thereby potentiating downstream signaling from the receptor. This is manifested by increased levels of phosphorylated receptor substrates and augmented steady-state pools of internalized, activated receptors. In a reciprocal fashion, activated receptors can mediate activation and translocation of c-Src to the cytoskeleton, where it phosphorylates several substrates, including cortactin, p130 $\zeta$ S, and p190RhoGAP. These substrates are central to regulation of actin cytoskeleton rearrangements and thus signals that control morphological transformation and migration. c-Src also contributes to neoplastic development through cell-cell adhesion signaling and up-regulation of gene transcription. Similar types of interactions are thought to occur with other receptor tyrosine kinases known to associate with c-Src.

is required for growth. c-Src and v-Src have also been shown to up-regulate transcription of vascular endothelial growth factor (VEGF) (Rak *et al.*, 1995; Mukhopadhyay *et al.*, 1995a,b; Weissenberger *et al.*, 1997). VEGF is a multifunctional cytokine that alters the pattern of gene expression and stimulates the proliferation and migration of endothelial cells that line the walls of microcapillaries. VEGF treatment also renders these same cells hyperpermeable, thereby allowing plasma proteins access to the extracapillary space. This process, in turn, leads to profound alterations in the extracellular matrix that favor angiogenesis (reviewed in Klagsbrun and D'Amore, 1996). Another potent modulator of angiogenesis (reviewed in Tkachuk *et al.*, 1997) is urokinase-type plasminogen activator (UPA), whose expression is up-regulated by v-Src (Bell *et al.*, 1990, 1993) and whose receptor is found in complex with c-Src family members (Bohuslav *et al.*, 1995). The ability of c-Src to influence gene transcription is a new and emerging question that is receiving considerable attention. However, most of the investigations that focus on the role of c-Src in neoplastic transformation have focused on substrates of c-Src and their contributions to development of the malignant phenotype. c-Src has a number of characterized substrates, most of which have functional connections to the actin cytoskeleton. These different substrates and their potential roles in transformation are discussed below.

## 2. TARGETS THAT SERVE AS SUBSTRATES OF c-Src

### a. Focal Adhesion Kinase

Focal adhesion kinase (FAK) is a cytoplasmic tyrosine kinase that localizes to focal adhesions and contributes to the processes of integrin-mediated cell spreading and migration through regulation of actin cytoskeleton remodeling (reviewed in Parsons and Parsons, 1997). FAK becomes tyrosine phosphorylated in response to various environmental stimuli, such as extracellular matrices and polypeptide and neuropeptide growth factors (reviewed in Schaller and Parsons, 1994). c-Src is intimately involved in FAK-mediated signaling. Activated c-Src (Y527F) is complexed with FAK through binding of the c-Src SH2 domain to Y397, the FAK autophosphorylation site (Schaller *et al.*, 1994; Cobb *et al.*, 1994). In addition, wt c-Src appears to be required for the FAK-mediated, integrin stimulation of mitogen-activated protein kinase (MAPK) (Schlaepfer and Hunter, 1997). Introduction of the amino-terminal half of c-Src, which lacks the kinase domain, reconstitutes integrin-induced MAPK activation in c-Src  $-/-$  fibroblasts, thus the process appears to be independent of c-Src kinase activity (Schlaepfer *et al.*, 1997).

### Cortactin

This finding suggests a potential role for c-Src as a docking protein. The role of c-Src in cell spreading also appears to be independent of the kinase domain, because defects in spreading of fibroblasts derived from c-Src null mice can be restored by the SH2 and SH3 domains but not by the catalytic do-

main of c-Src (Kaplan *et al.*, 1994, 1995). These findings suggest that even though c-Src is activated in response to mitogenic factors such as EGF and TGF, it may require only the redistribution of c-Src to focal adhesions to stimulate motility and focal adhesion turnover.

Given that FAK is known to transduce signals involved in the regulation of cell adhesion and motility as well as the anchorage-independent growth of transformed cells, it would not be unexpected to find aberrant expression of FAK in human tumors. Indeed, increased expression or activation of FAK is observed in a number of human tumors, including sarcomas and carcinomas of the breast, prostate, and colon (Weiner *et al.*, 1994; Owens *et al.*, 1995; Withers *et al.*, 1996; Tremblay *et al.*, 1996). As might be expected with involvement of FAK in motility, the highest levels of FAK are seen in metastatic or invasive lesions (Weiner *et al.*, 1994; Owens *et al.*, 1995; Tremblay *et al.*, 1996). An increase in FAK phosphorylation also correlates with increased migration and invasiveness of squamous cell carcinoma cells treated with HGF (Matsuimoto *et al.*, 1994). Together, the evidence suggests that signaling through FAK/c-Src complexes in normal and malignant cells is bidirectional. Integrins activate FAK, which can signal through c-Src to activate JNK2, or conversely, engaged growth factor receptors activate c-Src, which can then signal through FAK to mediate morogenic or cytoskeletal responses.

b. p130Cas

p130Cas (CAS) was first identified as a highly tyrosine-phosphorylated

protein in cells transformed by a variety of oncogenes (Mayer and Hanafusa, 1990; Auvinen *et al.*, 1995; Salgia *et al.*, 1996) and in normal cells following activation of integrins (Nojima *et al.*, 1995; Perch *et al.*, 1995; Vuori *et al.*, 1996) and stimulation with mitogenic neuropeptides, such as bombesin, asopressin, and endorphelin (Zachary *et al.*, 1992; Seufferlein and Rozenburg, 1994). The role of CAS in integrin or growth factor-mediated signaling is not understood. However, recent evidence indicates that CAS functions as an adapter molecule, binding a number of signaling molecules that participate in cell adhesion, such as FAK (Polte and Hanks, 1995; Harte *et al.*, 1996), PTP-PEST (Garton *et al.*, 1997), and Src family kinases (Polte and Hanks, 1995; Nakamoto *et al.*, 1996). Tyrosine phosphorylation of CAS is increased on adhesion and is largely dependent on c-Src (Vuori *et al.*, 1996; Tamasaki *et al.*, 1996). Thus, the link between cell adhesion, the actin cytoskeleton, and tumorigenesis is repeated, and the common involvement of Src in both processes suggests that c-Src may be a critical factor that links them together.

The v-Src and c-Src substrate, p75/p80/p85 cortactin, is an actin-binding protein that contains five tandem repeats in the N terminus and an SH3 domain in the extreme C terminus (Wu *et al.*, 1991; Maa *et al.*, 1992; Wu and

Parsons, 1993). The N terminus is responsible for the *in vitro* binding to actin. *In vivo* phosphoamino acid analysis of cortactin from primary chick embryo cells reveals that it contains only serine and threonine phosphorylations, whereas it exhibits constitutive phosphorylation on tyrosine in addition to serine and threonine in cells transformed by activated c-Src (Y527F) (Wu *et al.*, 1991). In immortalized murine 10T1/2 fibroblasts, cortactin has a low basal level of tyrosine phosphorylation that is increased on both EGF stimulation and c-Src overexpression (Wilson and Parsons, 1990; Maa *et al.*, 1992). Cortactin has also been shown to be tyrosine phosphorylated in response to fibroblast growth factors (Zhan *et al.*, 1993, 1994). These observations suggest that cortactin may be a substrate of growth factor receptors as well as of c-Src or that c-Src mediates growth factor-induced tyrosine phosphorylation of cortactin. The findings that cortactin associates with the Src SH2 domain and colocalizes with v-Src in transformed cells (Okamura and Reich, 1995), and that increased tyrosine phosphorylation of cortactin is seen in CSK-deficient cells, favor the notion that c-Src and/or its family members are responsible for phosphorylating cortactin (Nada *et al.*, 1994; Thomas *et al.*, 1995). Interestingly, two phases of EGF-induced cortactin tyrosine phosphorylation can be observed in 10T1/2 cells, one occurring within 2–10 min following stimulation and another occurring later in G<sub>1</sub>, with the maximum level seen approximately 9 hr posttreatment. In both cases, the level of phosphorylation is increased by overexpression of c-Src (Maa *et al.*, 1992). These observations raise the question of whether cortactin may function in mid-late G<sub>1</sub> as well as in immediate-early G<sub>1</sub>.

Indirect immunofluorescence microscopy of 10T1/2 cells reveals that cortactin is localized within the cytoplasm to punctate sites that are concentrated around the nucleus and colocalized with actin at the plasma membrane and peripheral adhesion site (Maa *et al.*, 1992). This pattern is not altered on EGF treatment or c-Src overexpression in 10T1/2 cells. However, in v-Src- or Y527F-c-Src-transformed cells, cortactin is localized to modified focal adhesions, termed podosomes. The appearance of podosomes is associated with loss of adhesive properties (Marchisio *et al.*, 1987; Wu *et al.*, 1991). Cortactin is also localized to podosome-like cell matrix sites in human tumors that overexpress the protein (including carcinomas of the breast and head and neck) (Schuurings *et al.*, 1992; Brookes *et al.*, 1993; Williams *et al.*, 1993; Schuurings *et al.*, 1993; Meredith *et al.*, 1995; Campbell *et al.*, 1996; van Damme *et al.*, 1997). From these observations, it follows that abnormal subcellular distribution of cortactin in human carcinomas may play a role in deregulating important protein–protein interactions that may be required for the proper formation of cell matrix contact sites. In support of this hypothesis is the correlation of cortactin overexpression with increased invasiveness, metastasis, and a poorer patient prognosis (Williams *et al.*, 1993; Meredith *et al.*, 1995; Takes *et al.*, 1997).

#### d. p190RhoGAP

p190RhoGAP was first identified as a tyrosine-phosphorylated protein that coprecipitates with p120RasGAP from v-Src-transformed Rat-2 cells (Ellis *et al.*, 1990). p190 has an N-terminal domain that binds GTP (Settleman *et al.*, 1992b; Foster *et al.*, 1994) and a C-terminal GTPase-activating domain (GAP) that is specific for small GTP-binding proteins of the Rho family (Settleman *et al.*, 1992a). p190 is functionally linked to the actin cytoskeleton through its ability to stimulate the conversion of Rho-GTP (which stimulates stress fiber formation) to Rho-GDP (which permits actin disassembly) (Ridley and Hall, 1992). Two phosphorylation sites, Y1087 and Y1105, in the middle portion of the molecule are postulated to mediate binding to the two SH2 domains of p120RasGAP (Bryant *et al.*, 1995; Hu and Settleman, 1997), although of the two sites, only Y1105 phosphorylation can be detected *in vivo*. Overexpression of c-Src in 10T1/2 cells results in an increase in the basal tyrosine phosphorylation of p190, specifically at Y1105 (Roof *et al.*, 1998). This evidence, along with the findings that overexpression of kinase-deficient c-Src decreases the phosphorylation at Y1105 and that c-Src phosphorylates Y1105 *in vitro*, suggests that c-Src is directly responsible for phosphorylation of this residue. Levels of p190 tyrosine phosphorylation are generally correlated with levels of the p190/p120RasGAP complex that can be detected *in vivo*, suggesting that high levels of p190 tyrosine phosphorylation could bind more RasGAP, thereby sequestering RasGAP away from Ras and permitting Ras to remain in the active, GTP-bound state longer. This scenario is consistent with the role of c-Src as a comitogenic signaling partner of growth factor receptors.

Although EGF treatment of 10T1/2 cells does not cause a further increase in tyrosine phosphorylation of p190, it does cause a rapid (seconds to minutes) and transient redistribution of p190 from a diffuse cytoplasmic localization into concentric arcs that radiate away from the nucleus with a time course that mimics EGF-stimulated actin dissolution (Chang *et al.*, 1995). Overexpression of wt c-Src expands the window of time in which EGF-induced actin dissolution and p190 arc formation occur, whereas overexpression of kinase-deficient c-Src contract the window. These results correlate with the level of p190 tyrosine phosphorylation and implicate another role for c-Src in regulating cytoskeletal reorganization, possibly by inactivating Rho through activation and redistribution of p190RhoGAP.

#### <sup>2</sup>. Platelet Endothelial Cell Adhesion Molecule

Platelet endothelial cell adhesion molecule-1 (PECAM-1) is a 130-kDa glycoprotein of the immunoglobulin gene superfamily that localizes to points of contact between confluent endothelial cells (Newman *et al.*, 1990; Tanaka *et al.*, 1992). On induction of endothelial sheet migration, PECAM-1 becomes diffusely organized within the cytoplasm, and ectopic expression of

the gene inhibits cell migration, suggesting that translocation from the periphery to the cytoplasm is a mechanism by which the inhibitory action of PECAM-1 is relieved (Schimmenti *et al.*, 1992). The cytoplasmic tail of PECAM-1 is critical for cell surface activity (DeLisser *et al.*, 1994; Yan *et al.*, 1995). It contains immunoreceptor tyrosine-based activation motifs (ITAMS) that are phosphorylated by c-Src *in vitro* and *in vivo* and bind c-Src SH2 domains *in vitro* (Lu *et al.*, 1997). Several lines of evidence suggest that tyrosine phosphorylation is involved in transducing cell migration signals through this molecule (Lu *et al.*, 1996; Pinter *et al.*, 1997). Tyrosines 663 and 686 appear to be the major sites of tyrosine phosphorylation, because mutation of either residue results in a drastic reduction in tyrosine phosphorylation, and mutation of Y686 is associated with a reversal of the PECAM-1-mediated inhibition of cell migration (Lu *et al.*, 1996). Again, phosphorylation by c-Src is a potential mechanism of regulation of a molecule involved in cell-cell contacts and migration, pointing to a role for both PECAM-1 and c-Src in angiogenesis and metastasis.

#### f. Other Substrates

Additional reports implicate still other c-Src substrates in cell-cell adhesion. Syndecan-1 is a cell surface proteoglycan that interacts with extracellular matrix molecules and growth factors to maintain epithelial cell morphology, anchorage-dependent growth, and inhibition of invasiveness in cell culture assays. The absence of this molecule correlates with a higher grade of transformation and poorer patient prognosis (Inki and Jalkanen, 1996). Its expression is negatively regulated at the level of translation on transformation by polyoma virus middle-T antigen. The effects of middle-T antigen are dependent on association with and activation of c-Src (Levy *et al.*, 1996). c-Src may also function in processes other than those related to cytoskeletal or adhesion dynamics but that still lead or contribute to a transformed phenotype. For example, a role for c-Src in mitosis has been implicated through the identification of a 68-kDa RNA-binding protein, called Sam68 (Src-associated in mitosis), that binds the SH3/2 domains of c-Src (reviewed in Courtneidge and Fumagalli, 1994) and is postulated to act through c-Src to regulate microtubule dynamics via association with (Abu-Amer *et al.*, 1997) and phosphorylation of (Matten *et al.*, 1990) tubulin.

inhibitors based on various structural and functional characteristics of the enzymes have been developed. First and foremost among these are inhibitors of catalytic activity. Among these inhibitors are the tyrophostins (Burke, 1992; Levitzki and Gazit, 1995), which compete with the protein substrate for access to the catalytic site; genistein (Akiyama *et al.*, 1987), a competitive inhibitor of ATP; lavendustin A and B (Onoda *et al.*, 1989); eristatin (Imoto *et al.*, 1987); and herbimycin A (Uehara *et al.*, 1986, 1989a,b), which has been shown to promote the ubiquitin-based degradation of the TKs (Sepp-Lorenzino *et al.*, 1995). Other inhibitors are designed to prevent interactions mediated through SH2 and SH3 domains (peptidomimetics) (Smithgall, 1995; Plummer *et al.*, 1996, 1997) or to prevent myristylation (*N*-fatty acyl-glycinal compounds) (Shoji *et al.*, 1990). In numerous cases these reagents have been demonstrated to be antiproliferative (Clark *et al.*, 1996; Traxler *et al.*, 1997; Hartmann *et al.*, 1997). In other instances membrane penetrance of the drug has been a problem in testing their efficacies in tissue culture and animal models (Gilmer *et al.*, 1994).

Studies characterizing the molecular interactions between c-Src and HER1 have revealed an additional target for drug design, specifically the sequences surrounding Y845 of HER1. Phosphorylation of this site by c-Src appears to be required for the mitogenic and tumorigenic aspect of receptor function, as shown by the inability of kinase-defective c-Src to phosphorylate Y845 and the nonfunctionality of the mutant Y845F receptor. In human tumors that overexpress c-Src and HER1, inhibiting the ability of c-Src to phosphorylate Y845 might reduce the tumorigenic potential of the overexpressed receptor as well as the ability of c-Src to synergize with the receptor. Such inhibition might be accomplished by a Y845 peptidomimetic. The advantages appear to be that this inhibition targets an enzyme/substrate interaction that occurs to the greatest degree in those cells that overexpress both players (c-Src and HER1, respectively), namely, cancer cells. In no normal cells are these two molecules known to be simultaneously overexpressed. For example, in the adult, the highest levels of c-Src are found in platelets (Golden *et al.*, 1986) and in cells of the nervous system, whereas high levels of HER1 are found in the liver and kidney (Nexo and Kryger-Baggesen, 1989). In theory, therefore, the Y845 peptidomimetic might be more likely to target the tumor cells than the normal cells, thus providing a potential "tumor-specific" drug for cancers such as carcinomas of the colon, breast, and lung.

## V. POTENTIAL THERAPEUTIC APPLICATIONS OF c-Src/HER1 INTERACTIONS

Along with the first evidence for possible roles for receptor and nonreceptor tyrosine kinases in human tumorigenesis has come the development of strategies to inhibit the functions of these classes of enzymes. A plethora of

# c-Src-mediated Phosphorylation of the Epidermal Growth Factor Receptor on Tyr<sup>845</sup> and Tyr<sup>1101</sup> Is Associated with Modulation of Receptor Function\*

(Received for publication, September 25, 1998, and in revised form, January 8, 1999)

Jacqueline S. Biscardi, Ming-Che Maa, David A. Tice, Michael E. Cox, Tzeng-Horne Leu,  
and Sarah J. Parsons†

From the Department of Microbiology and Cancer Center, Box 441, University of Virginia Health Sciences Center,  
Charlottesville, Virginia 22908

Accumulating evidence indicates that interactions between the epidermal growth factor receptor (EGFR) and the nonreceptor tyrosine kinase c-Src may contribute to an aggressive phenotype in multiple human tumors. Previous work from our laboratory demonstrated that murine fibroblasts which overexpress both these tyrosine kinases display synergistic increases in DNA synthesis, soft agar growth, and tumor formation in nude mice, and increased phosphorylation of the receptor substrates Shc and phospholipase  $\gamma$  as compared with single overexpressors. These parameters correlated with the ability of c-Src and EGFR to form an EGF-dependent heterocomplex *in vivo*. Here we provide evidence that association between c-Src and EGFR can occur directly, as shown by receptor overlay experiments, and that it results in the appearance of two novel tyrosine phosphorylations on the receptor that are seen both *in vitro* and *in vivo* following EGF stimulation. Edman degradation analyses and co-migration of synthetic peptides with EGFR-derived tryptic phosphopeptides identify these sites as Tyr<sup>845</sup> and Tyr<sup>1101</sup>. Tyr<sup>1101</sup> lies within the carboxyl-terminal region of the EGFR among sites of receptor autophosphorylation, while Tyr<sup>845</sup> resides in the catalytic domain, in a position analogous to Tyr<sup>416</sup> of c-Src. Phosphorylation of Tyr<sup>416</sup> and homologous residues in other tyrosine kinase receptors has been shown to be required for or to increase catalytic activity, suggesting that c-Src can influence EGFR activity by mediating phosphorylation of Tyr<sup>845</sup>. Indeed, EGF-induced phosphorylation of Tyr<sup>845</sup> was increased in MDA468 human breast cancer cells engineered to overexpress c-Src as compared with parental MDA 468 cells. Furthermore, transient expression of a Y845F variant EGFR in murine fibroblasts resulted in an ablation of EGF-induced DNA synthesis to nonstimulated levels. Together, these data support the hypothesis that c-Src-mediated phosphorylation of EGFR Tyr<sup>845</sup> is involved in regulation of receptor function, as well as in tumor progression.

The epidermal growth factor receptor (EGFR)<sup>1</sup> is a 170-kDa

<sup>1</sup> The abbreviations used are: EGFR, epidermal growth factor recep-

single-pass transmembrane tyrosine kinase that undergoes homo- or heterodimerization and enzymatic activation following ligand binding (1, 2). These events result in the trans-(auto)-phosphorylation of multiple Tyr residues in the COOH-terminal tail of the molecule that serve as binding sites for cytosolic signaling proteins containing Src homology 2 (SH2) domains (3). Five sites of *in vivo* autophosphorylation have been identified in the EGFR: three major (Tyr<sup>1068</sup>, Tyr<sup>1148</sup>, and Tyr<sup>1173</sup>) and two minor (Tyr<sup>992</sup> and Tyr<sup>1086</sup>) (4–7). These sites bind a variety of downstream signaling proteins which contain SH2 domains, including Shc (8) and PLC $\gamma$  (9). Binding of these or other signaling proteins to the receptor and/or their phosphorylation results in transmission of subsequent signaling events that culminate in DNA synthesis and cell division.

c-Src is a nonreceptor tyrosine kinase that functions as a co-transducer of transmembrane signals emanating from a variety of polypeptide growth factor receptors, including the EGFR (see Refs. 10 and 11, and reviewed in Ref. 12). Overexpression of wild type (wt) and dominant negative forms of c-Src in murine C3H10T1/2 fibroblasts that express normal levels of receptor, as well as experiments involving the microinjection of antibodies specific for Src family members, have revealed that c-Src is a critical component of EGF-induced mitogenesis (10, 11, 13). Cells which express high levels of EGFR become transformed upon continual exposure to EGF (14), and co-overexpression of c-Src in these cells dramatically potentiates their growth and malignant properties (15). Together, these findings indicate that c-Src co-operates with the EGFR in the processes of both mitogenesis and transformation.

Subsequent studies in 10T1/2 cells revealed that potentiation of EGF-induced growth and tumorigenesis by c-Src, which is observed only in cells overexpressing both c-Src and the receptor, correlates with the EGF-dependent formation of a heterocomplex containing c-Src and activated EGFR, the appearance of two unique *in vitro* non-autophosphorylation sites on receptors in complex with c-Src, and enhanced *in vivo* tyrosyl phosphorylation of the receptor substrates, PLC $\gamma$  and Shc (15). These findings suggested that c-Src-dependent phosphorylations on the EGFR can result in hyperactivation of receptor kinase activity, as measured by the enhanced ability of the receptor to phosphorylate its cognate substrates. This report identifies Tyr<sup>845</sup> and Tyr<sup>1101</sup> as c-Src-dependent sites of phosphorylation, which are present both *in vitro* and *in vivo* in receptor from 10T1/2 double overexpressing fibroblasts and

tor; DMEM, Dulbecco's modified Eagle's medium; CHAPS, 3-[{3-cholamidopropyl}dimethylammonio]-1-propanesulfonic acid; PLC $\gamma$ , phospholipase  $\gamma$ ; PIPES, 1,4-piperazinediethanesulfonic acid; PAGE, polyacrylamide gel electrophoresis; HPLC, high performance liquid chromatography; BrdUrd, bromodeoxyuridine; GST, glutathione S-transferase; mAb, monoclonal antibody.

from MDA468 human breast cancer cells. In the MDA468 cells, overexpression of c-Src results in a further increase in the phosphorylation of Tyr<sup>845</sup>, indicating that c-Src either phosphorylates this site directly or activates a secondary kinase which is responsible. Moreover, cells which transiently express EGFR bearing a Tyr to Phe mutation at Tyr<sup>845</sup> are impaired in their ability to synthesize DNA in response to EGF, suggesting that this c-Src mediated phosphorylation site is important for receptor function.

#### MATERIALS AND METHODS

**Cell Lines**—The derivation and characterization of the clonal C3H10T1/2 murine fibroblast cell lines used in this study, Neo (control), 5H (c-Src overexpressor), NeoR1 (human EGFR overexpressor), and 5HR11 (c-Src/EGFR double overexpressor) have been described previously (10, 11, 13). 5H and 5HR11 express equal levels of c-Src (~25-fold over endogenous), and NeoR and 5HR11 express nearly equal levels of cell surface receptors (~2 × 10<sup>5</sup> receptors/cell or ~40-fold over endogenous). Cells were maintained in Dulbecco's modified Eagle's medium (DMEM, Life Technologies, Inc., Gaithersburg, MD), containing 10% fetal calf serum, antibiotics, and G418 (400 µg/ml). When indicated, confluent cultures were starved of serum overnight, prior to stimulation with 100 ng/ml purified mouse EGF (Sigma).

To create cells transiently overexpressing HER1 which contained a Tyr to Phe mutation at position 845, a *Dra*III-*Bst*EII fragment from pCO11 (gift of Laura Beguinot), including the mutation at position 845, was subcloned into a pcDNA vector containing wild type human HER1 (gift of Dr. Stuart Decker, Parke Davis, Ann Arbor, MI). Neo control 10T1/2 fibroblasts were transiently transfected with 30 µg of Superfect (Qiagen, Chatsworth CA) and 4 µg of vector, wt HER1, or Y845F HER1 plasmid DNA according to the manufacturers' directions and incubated for 48 h.

For overexpression of c-Src in breast cancer cells, pcDNAc-Src was constructed by inserting the c-Src *Xba*I fragment from an existing pVZneo vector into the multicloning site of pcDNA3 (Invitrogen, San Diego, CA). MDA468 cells, obtained from N. Rosen (Sloan Kettering Cancer Center, New York), were maintained in DMEM plus 5% serum. MDA468 cells stably overexpressing chicken c-Src (clone MDA468c-Src) were generated by Lipofectin™ (Life Technologies, Inc.)-mediated gene transfer of pcDNAc-Src into parental MDA468 cells and selection with 400 µg/ml G418. Parental MDA468 cells overexpress c-Src approximately 5-fold, as compared with Hs578Bst normal breast epithelial cells, and contain approximately 10<sup>6</sup> receptors/cell (Ref. 16),<sup>2</sup> while MDA468c-Src cells overexpress c-Src approximately 25-fold over levels found in normal breast epithelial cells.

**Antibodies**—EGFR-specific mouse monoclonal antibodies (mAbs) 3A and 4A were provided by D. McCarley and R. Schatzman of Syntex Research, Palo Alto, CA. Their derivation has been described previously and their epitopes have been mapped to residues 889–944 and 1052–1134, respectively. EGFR-specific mAb F4, directed against amino acids 985–996, was obtained from Sigma. GD11 antibody is directed against the SH3 domain of c-Src and was characterized previously in our laboratory (17, 18). Q9 antibody was raised in rabbits against the COOH-terminal peptide of c-Src (residues 522–533) and exhibits a higher affinity for c-Src than for other Src family members (19, 20). Antiphosphotyrosine (Tyr(P)) antibody (4G10) was purchased from UBI (Lake Placid, NY). Negative control antibodies included pooled and purified normal rabbit or mouse immunoglobulin.

**Immunoprecipitation, Western Immunoblotting, and in Vitro Kinase Assays**—Methods for immunoprecipitation, Western immunoblotting, and *in vitro* kinase assays have been described previously (10, 11, 15). Cells were lysed either in CHAPS detergent buffer (10 mM CHAPS, 50 mM Tris-HCl, pH 8.0, 150 mM NaCl, 2 mM EDTA, 1 mM sodium orthovanadate, 1 mM phenylmethylsulfonyl fluoride, 50 µg/ml leupeptin, and 0.5% aprotinin), or in RIPA detergent buffer (0.25% sodium deoxycholate, 1% Nonidet P-40, 50 mM Tris-HCl, pH 7.2, 150 mM NaCl, 2 mM EDTA, 1 mM sodium orthovanadate, 50 µg/ml leupeptin, and 0.5% aprotinin). Protein concentrations of detergent lysates were determined by the BCA protein assay (Pierce, Rockford, IL). 500 µg of cell lysate was used for immunoprecipitations, and 50 µg was used for Western blotting. For Western immunoblotting, binding of primary murine or rabbit antibodies to Immobilon membranes was detected with either <sup>125</sup>I-labeled goat anti-mouse IgG (NEN Life Science Products Inc.) or <sup>125</sup>I-protein A (NEN) used at 1 µCi/ml specific activity 100 µCi/ml. For

kinase assays, immunoprecipitates were prepared in and washed twice in CHAPS buffer, then washed twice with HBS buffer (150 mM NaCl, 20 mM HEPES, pH 7.4). Each kinase reaction was conducted in 20-µl volumes containing 20 mM PIPES, pH 7.5, 10 mM MnCl<sub>2</sub>, and 10 µCi of [ $\gamma$ -<sup>32</sup>P]ATP (6000 Ci/mmol, NEN) for 10 min at room temperature. Incubations were terminated by addition of sample buffer, and labeled products were resolved by SDS-PAGE and visualized by autoradiography.

**In Vitro Binding and Far Western Analysis Using GSTc-SrcSH2**—The construction and preparation of GST fusion proteins containing the SH2 domain of c-Src was described previously (21). To reconstitute binding between tyrosyl-phosphorylated EGFR and the SH2 domain of c-Src, 2 µg of immobilized GST-c-SrcSH2 fusion protein was incubated with 100 µg of 10T1/2 cell lysate protein prepared in RIPA buffer. After 3 h gentle mixing at 4 °C, beads were washed three times with RIPA buffer, resuspended in SDS sample buffer, and boiled. Eluted proteins were separated by SDS-PAGE, transferred to Immobilon, and immunoblotted with either the Tyr(P) or the 3A/4A or F4 (Sigma) monoclonal EGFR antibodies.

To assess direct binding of GST-c-SrcSH2 to the EGFR, receptor from 500 µg of cell lysate protein in RIPA buffer was immunoprecipitated with 3A/4A mAbs. The resulting EGFR immunoprecipitates were resolved by SDS-PAGE, transferred to Immobilon membranes, and incubated with 1 mg/ml purified GST-c-SrcSH2 fusion protein in blocking buffer at 4 °C overnight. The membrane was then probed with 1 µg/ml affinity purified, polyclonal rabbit anti-GST antiserum in blocking buffer,<sup>3</sup> and immunoglobulin binding was detected by <sup>125</sup>I-protein A.

**Metabolic Labeling**—NeoR1 or 5HR11 cells were grown to 50–75% confluence in 150-mm dishes, washed with phosphate-free DMEM, and incubated for 18 h in phosphate-free DMEM containing 0.1% dialyzed fetal bovine serum and 1 mCi/ml [<sup>32</sup>P]orthophosphate (NEN Life Sciences Products Inc.) in a final volume of 10 ml. For pervanadate treatment, labeling medium was adjusted to a concentration of 3 mM H<sub>2</sub>O<sub>2</sub> and 5 µM Na<sub>3</sub>VO<sub>4</sub> just prior to EGF stimulation. Cells were stimulated in the presence of pervanadate by addition of 100 ng/ml EGF to the labeling medium for 5 min, washed twice with phosphate-free DMEM, and lysed in CHAPS detergent buffer. Extract from an entire plate (approximately 1–2 mg of protein) was immunoprecipitated with c-Src or EGFR-specific antibodies as described above.

**Two-dimensional Tryptic Phosphopeptide Analysis**—Immunoprecipitates of *in vitro* or *in vivo* <sup>32</sup>P-labeled EGFR were resolved by SDS-PAGE. The EGFR was localized by autoradiography, excised from the gel, and digested with trypsin as described by Boyle *et al.* (22). Phosphotryptic peptides were separated by electrophoresis at pH 1.9 in the first dimension and ascending chromatography in the second dimension on cellulose thin layer chromatography (TLC) plates. Chromatography buffer contained isobutyric acid, 1-butanol, pyridine, acetic acid, H<sub>2</sub>O (125:3.8:9.6:5.8:55.8). Migration of synthetic phosphopeptides was detected by spraying the dried TLC plate with a hypochlorite solution consisting of sequential sprays with 10% commercial Clorox, 95% ethanol, 1% potassium iodide, and saturated *o*-toluidine in 1.5 M acetic acid, as described in Stewart and Young (23).

**High Performance Liquid Chromatography (HPLC)**—For HPLC analysis of peptides derived from the EGFR associated with c-Src, <sup>32</sup>P-labeled phosphotryptic peptides were prepared as above and suspended in 0.05% trifluoroacetic acid. Peptides were injected into a Perkin-Elmer Series 4 Liquid Chromatograph equipped with a Vydac C18 column (4.6 × 250 mm) and eluted with increasing concentrations of acetonitrile (0 to 100%) at a flow rate of 1 ml/min, as described by Wasilenko *et al.* (24). 500-µl fractions were collected, and Cerenkov counts of each fraction were determined. Fractions containing peptides "0" and "3" were identified by two-dimensional TLC analysis for their ability to co-migrate with the appropriate peptide in a mixture of total *in vitro* phosphorylated receptor peptides. Appropriate fractions were then lyophilized and subjected to Edman degradation.

**Edman Degradation**—HPLC fractions of <sup>32</sup>P-labeled EGFR phosphotryptic peptides or spots eluted from TLC plates were subjected to automated Edman degradation, as performed by the University of Virginia Biomolecular Research Facility. Briefly, phosphorylated peptides were coupled to a Sequelon aryl amine membrane (25), washed with 4 × 1 ml of 27% acetonitrile, 9% trifluoroacetic acid, and 2 × 1 ml of 50% methanol, and transferred to an applied Biosystems 470A sequenator using the cartridge inverted as suggested by Stokoe *et al.* (26). The cycle used for sequencing was based on that of Meyer *et al.* (27), but modified

<sup>2</sup> N. Rosen, personal communication.

<sup>3</sup> J. H. Chang and S. Parsons, unpublished data.

by direct collection of anilinothiazolinone amino acids in neat trifluoroacetic acid as described by Russo *et al.* (28). Radioactivity was measured by Cerenkov counting.

**Identification of Peptides 0 and 3**—Phosphorylated peptides (corresponding to residues GMN(Y-P)LEDR, candidate for peptide 3; or E(Y-P)HAEGGK, candidate for peptide 0) were synthesized by the University of Virginia Biomolecular Research Facility. Synthetic peptides were mixed with oxidized *in vitro* labeled phosphotryptic peptides from c-Src-associated EGFR, separated on cellulose TLC plates, and visualized by spraying with the hypochlorite solution as described above. One candidate for peptide 3 (GMNYLEDR) was synthesized as a phosphopeptide and tested for comigration as above. Another candidate for peptide 3 (DPHY<sup>101</sup>QDPHSTAVGNPEYLNTVQPTCVNSTF DSPAH-WAQK), which was too large to chemically synthesize, was tested by further digestion of *in vitro* labeled peptide 3 with a proline-directed protease (Seikagaku, Rockville, MD), according to the method of Boyle *et al.* (22). In brief, the spot corresponding to peptide 3 was scraped off the TLC plate, eluted with pH 1.9 buffer, and digested with 5 units of proline-directed protease in 50 mM ammonium bicarbonate at pH 7.6 at 37 °C for 1 h. Peptides were separated by two-dimensional electrophoresis as described above.

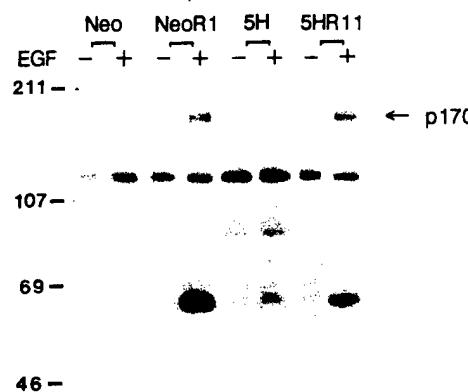

**BrdUrd Incorporation**—Neo control cells, which had been transfected with cDNAs encoding wild type EGFR, Y845F EGFR, or vector alone were cultured for 48 h, then serum starved for an additional 30 h prior to the administration of 100 μM BrdUrd and either 100 ng/ml EGF or 10% fetal calf serum in fresh growth medium. Treated cells were incubated for 18 h and co-stained for HER1 expression and BrdUrd incorporation as described by the manufacturer of the BrdUrd-specific antibody (Boehringer Mannheim). Briefly, fixed cells were treated with 2 N HCl for 1 h at 37 °C and incubated with a mixture of primary antibodies (1:100 dilution of the HER1-specific Ab-4, and a 1:15 dilution of anti-BrdUrd mouse antibody in serum-free medium for 1 h at 37 °C), followed by incubation with a mixture of secondary antibodies (75 μg/ml fluorescein isothiocyanate-conjugated goat anti-rabbit IgG and 4 μg/ml Texas Red-conjugated goat anti-mouse IgG) for 1 h at 37 °C. Both secondary reagents were obtained from Jackson Immunoresearch Laboratories, West Grove, PA.

## RESULTS

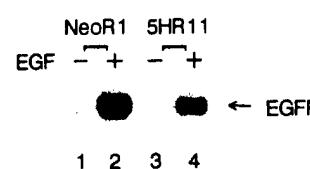

**Direct Binding of c-Src SH2 Domain to the EGFR**—Previous work from our laboratory demonstrated a synergistic interaction between c-Src and the EGFR which led to increased cell growth and tumor development (10, 11, 15). This functional synergism was most striking when cells overexpressed both c-Src and the EGFR (5HR cells) and correlated with the ability of c-Src and the EGFR to form specific, EGF-dependent heterocomplexes *in vivo*. The formation of this c-Src·EGFR complex raises the question of whether binding between c-Src and the EGFR occurs directly, or is mediated by another protein present in the complex. To test whether association could be mediated by a Tyr(P)-SH2 interaction, lysates from unstimulated and stimulated Neo, 5H, NeoR, or 5HR cells were incubated with a GST-c-SrcSH2 bacterial fusion protein linked to agarose beads, and precipitated proteins were probed with Tyr(P) antibody. Fig. 1, panel A, lanes 4 and 8, show that a tyrosyl-phosphorylated protein of 170 kDa was precipitated by GST-c-SrcSH2 from extracts of cells overexpressing the EGFR after activation of the receptor with EGF. This 170-kDa protein co-migrated with the EGFR precipitated with receptor-specific mAbs 3A/4A (data not shown). Other proteins that bound c-SrcSH2 included p125<sup>FAK</sup> (21), which was detected in all the cell lysates, a 75–80-kDa protein, cortactin, which was most prominent in 5H cells (30), and a 62-kDa protein, presumed to be related to the 62-kDa “DOK” protein associated with p120<sup>Ras-GAP</sup> (31–34). These results suggest that *in vivo*, multiple Tyr(P)-containing proteins in addition to the EGFR are capable of interacting with c-Src via its SH2 domain and contribute to the highly tumorigenic phenotype of the double overexpressing cells. Incubation of cell extracts with GST-beads alone resulted in no detectable binding of Tyr(P)-containing proteins (data not shown).

To confirm that the 170-kDa protein was indeed the EGFR,

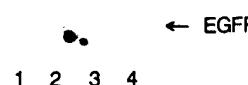

## A src-SH2 IP/p-Tyr blot

## B src-SH2 IP/EGFR blot

## C EGFR IP/src-SH2 blot

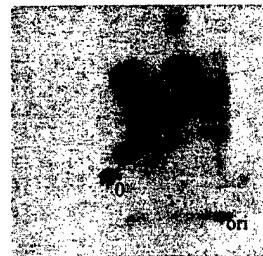

## D EGFR IP/EGFR blot

**FIG. 1. *In vitro* association between activated EGFR and c-Src SH2 domain.** 500 μg of lysate protein from the indicated nonstimulated cells or cells stimulated with 100 ng/ml EGF for 2 min was incubated with GST-c-SrcSH2 fusion protein immobilized on glutathione-agarose beads (*Panels A* and *B*) or EGFR mAbs 3A/4A bound to Protein A (*Panels C* and *D*), as described under “Materials and Methods.” Affinity-purified proteins were washed and subjected to SDS-PAGE, transferred to Immobilon membranes, and probed with: *A*, Tyr(P) mAb 4G10; *B*, EGFR mAbs 3A/4A; *C*, GST-c-Src SH2 fusion protein; and *D*, EGFR mAb 3A/4A. Binding of primary antibody was visualized by incubating membranes with <sup>125</sup>I-labeled goat anti-mouse IgG (*Panels A*, *B*, and *D*), and binding of GST-c-SrcSH2 fusion protein was detected by rabbit anti-GST and <sup>125</sup>I-protein A (*Panel C*). GST-c-SrcSH2 fusion protein is shown to bind directly to activated EGFR.

lysates prepared from unstimulated and stimulated NeoR and 5HR cells were precipitated with immobilized GST-c-SrcSH2, and bound proteins were immunoblotted with EGFR-specific mAbs 3A/4A. Fig. 1, *Panel B*, demonstrates that receptor antibody detected the 170-kDa protein only in stimulated cells, as in *Panel A*, confirming its identity as the EGFR. To test if the interaction between the activated EGFR and c-SrcSH2 could be direct, receptor immunoprecipitates were subjected to a “Far Western” overlay experiment, using GST-c-SrcSH2, GST-specific antibody, and <sup>125</sup>I-protein A. Fig. 1, *Panel C*, lanes 2 and 4, shows that GST-c-SrcSH2 bound the EGFR and, as predicted, the interaction required activation by EGF. GST alone exhibited no binding (data not shown). *Panel D* verified that nearly equal amounts of receptor were present in all immunoprecipitates. These results provide evidence for the involvement of SH2-Tyr(P) interactions in the formation of the EGFR-c-Src complex.

*In Vivo and in Vitro Phosphorylation of Novel, Non-auto-*

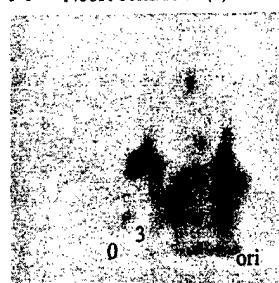

Phosphorylation of EGF Receptor on Tyr<sup>845</sup> and Tyr<sup>1101</sup>A. NeoR R *in vitro*B. 5HR Src/R *in vitro*C. 5HR Src/R *in vivo*+ PV

**FIG. 2. EGFR phosphotryptic peptides radiolabeled *in vitro* or *in vivo*.** For *in vitro* labeling (Panels A and B), 5HR and NeoR cells were stimulated with 100 ng/ml EGF for 30 min, followed by lysis in CHAPS buffer and immunoprecipitation of extract proteins with either c-Src-specific (GD11) or EGFR-specific (3A/4A) antibody. Precipitated proteins were then subjected to an *in vitro* kinase reaction, and products were analyzed by SDS-PAGE and autoradiography. For *in vivo* experiments (Panel C), cells were labeled for 18 h in phosphate-free media containing [<sup>32</sup>P]orthophosphate, stimulated with 100 ng/ml EGF for 5 min in the presence of pervanadate, and lysed in CHAPS buffer. Extracts were immunoprecipitated with GD11 antibody, and precipitated proteins were analyzed by SDS-PAGE and autoradiography. c-Src-associated, <sup>32</sup>P-labeled EGFR was eluted from gel slices, and samples were trypsinized and analyzed by two-dimensional TLC as described previously (17). Labeled peptides were visualized by autoradiography. Panel A, *in vitro* labeled EGFR immunocomplexes from NeoR cells (2000 cpm); Panel B, *in vitro* labeled c-Src-associated EGFR from 5HR cells (2000 cpm); Panel C, c-Src-associated EGFR from 5HR cells labeled *in vivo* (3000 cpm). Tryptic maps were exposed to Pegasus Blue film (Pegasus, Burtonsville, MD) for 18 h.

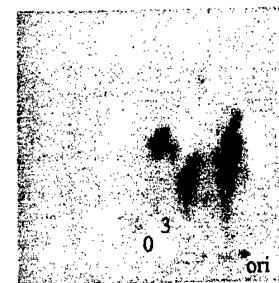

**phosphorylation Sites on the EGFR in Complex with c-Src—** Overexpression of both EGFR and c-Src in 10T1/2 cells results in increased tyrosyl phosphorylation of receptor substrates, PLC $\gamma$  and Shc, following EGF treatment (15). These findings suggest that the c-Src-associated receptor is modified in some manner as to increase its kinase activity. To examine the receptor for novel phosphorylations, the *in vitro* phosphorylated, c-Src-associated 170-kDa protein was excised from the gel and subjected to two-dimensional phosphotryptic peptide analysis. The phosphopeptide map of c-Src-associated receptor was then compared with the map of the free receptor, immunoprecipitated with receptor antibody. Fig. 2, Panels A and B, demonstrate that the maps are nearly identical; however, two additional phosphorylations (designated peptides 0 and 3) were seen in the map of the EGFR complexed with c-Src, suggesting that c-Src was responsible for their phosphorylation. Consistent with this notion, two-dimensional phosphoamino acid analysis of the *in vitro* labeled EGFR demonstrated that peptides 0 and 3 contained only phosphotyrosine (data not shown). Panel C shows that the two novel phosphopeptides were also detected in the receptor found in complex with c-Src from <sup>32</sup>P metabolically labeled 5HR cells that had been treated with pervanadate and EGF for 5 min. These data indicate that two phosphorylations occur on the EGFR both *in vitro* and *in vivo* when c-Src becomes physically associated with the receptor following EGF stimulation.

Initial attempts to detect peptides 0 and 3 in receptor immunoprecipitations from <sup>32</sup>P-labeled NeoR or 5HR cells yielded phosphopeptide maps that contained peptide 3 but no or barely detectable levels of peptide 0 (Fig. 3, Panels A and C). Neither could peptide 3 nor peptide 0 be detected reproducibly in receptor that was associated with c-Src from 5HR cells (data not shown). Furthermore, in receptor immunoprecipitations, the levels of peptide 3 derived from NeoR versus 5HR cells appeared nearly equal (compare Panels A and C), suggesting that peptide 3 may not be an *in vivo*, c-Src-dependent site of phosphorylation. In these experiments, lysates were prepared in CHAPS buffer containing a mixture of conventional protease and phosphatase inhibitors, including orthovanadate (see "Materials and Methods"). However, modification of the EGF treatment regimen to include pervanadate during stimulation allowed us to detect peptide 0 in receptor immunoprecipitates from NeoR (Panel B) and 5HR (Panel D) cells. These conditions revealed more peptide 0 in receptor from 5HR than from NeoR cells, confirming the ability of c-Src to modulate the phosphorylation of this peptide. Of special note was the finding that peptide 0 was the only peptide seen to increase in phosphoryl-

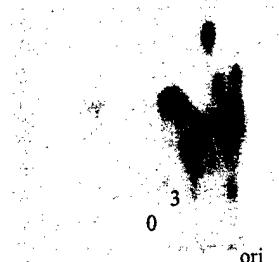

A NeoR cells/R IP (-) PV

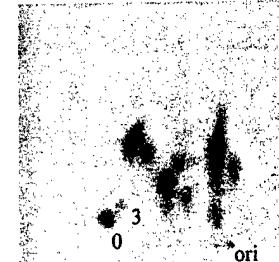

B NeoR cells/R IP +PV

C 5HR cells/R IP (-) PV

D 5HR cells/R IP +PV

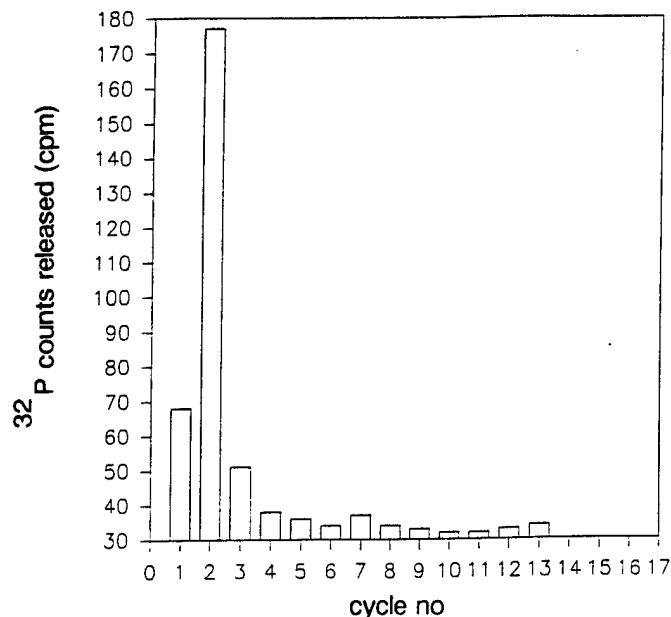

**FIG. 3. Phosphorylation of peptides 0 and 3 in metabolically labeled pervanadate-treated cells.** NeoR and 5HR cells were incubated for 18 h with [<sup>32</sup>P]orthophosphate as above. Pervanadate (3 mM H<sub>2</sub>O<sub>2</sub> and 5  $\mu$ M Na<sub>3</sub>VO<sub>4</sub>) was added (Panels B and D) or not (Panels A and C) along with 100 ng/ml EGF for 5 min prior to lysis in RIPA detergent buffer. EGFR was immunoprecipitated with mAbs 3A/4A, and the receptor was processed for phosphotryptic analysis as described in the legend to Fig. 3. Panel A, EGFR from NeoR cells; Panel B, EGFR from pervanadate-treated NeoR cells; Panel C, EGFR from 5HR cells; Panel D, EGFR from pervanadate-treated 5HR cells. ~3000 cpm were loaded per TLC plate. TLC plates were exposed to Pegasus blue film for 18 h.

ation in response to pervanadate treatment, suggesting that its phosphorylation is more labile than that of peptide 3 or the other phosphorylations on the receptor, which presumably correspond to autophosphorylation sites. Together with the *in vitro* studies depicted in Fig. 2, the results from the *in vivo* experiments indicate that peptide 0 is an *in vitro* and *in vivo* site of receptor phosphorylation that is regulatable by c-Src. Following this line of reasoning, the low level of peptide 0 phosphorylation seen in receptor immunoprecipitates from NeoR cells (Fig. 3, Panel B) could be due to endogenous c-Src. However, the involvement of other tyrosine kinases in the *in vivo* phosphorylation of peptide 0 cannot be ruled out.

Whether c-Src alone plays a role in regulating the phospho-

## A peptide "0"

## B peptide "3"

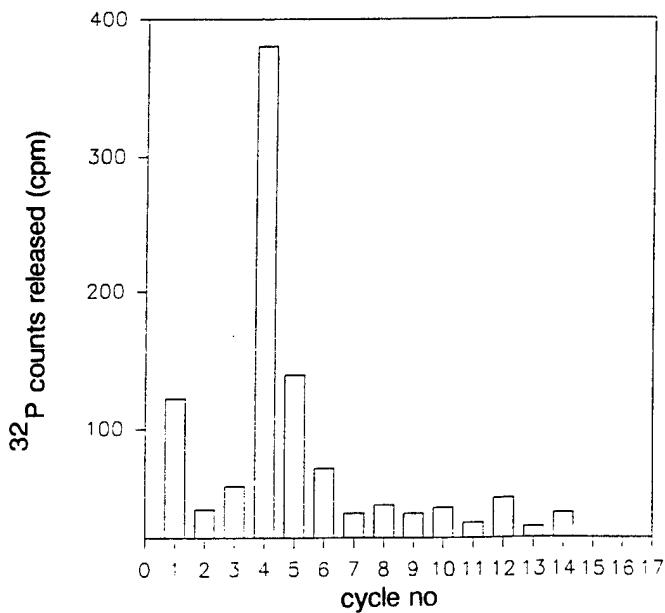

FIG. 4. Edman degradation of peptides 0 and 3. Peptides 0 and 3 were isolated by HPLC and subjected to automated Edman analysis. A, <sup>32</sup>P from peptide 0 was released at the second cycle, indicating a phosphorylated tyrosine at position 2; B, <sup>32</sup>P from peptide 3 was released at the fourth cycle, indicating a phosphorylated tyrosine at position 4.

rylation of peptide 3 *in vivo* is less clear. *In vitro*, peptide 3 phosphorylation appears to be unique to the receptor associated with c-Src (compare Panels A and B of Fig. 2), and HPLC analysis corroborates this, where phosphorylation of the peak corresponding to peptide 3 was found to be ~3.5-fold greater when the receptor was associated with c-Src *versus* free receptor (data not shown). Furthermore, the level of *in vivo* phosphorylation of peptide 3 in the c-Src-associated receptor is greater than that found in the "free" receptor (compare Fig. 2, Panel C, with Fig. 3, Panel D). However, peptide 3 is readily detected in free receptor labeled *in vivo*, and its level of phosphorylation does not appear to increase to any great extent in 5HR *versus* NeoR cells (Fig. 3, Panels B and D). These data can be interpreted to mean either that peptide 3 contains a non-labile site of phosphorylation, regulatable by c-Src (in contrast to peptide 0), or that phosphorylation of peptide 3 may be

regulated by an additional tyrosine kinase *in vivo*.

To identify the amino acids phosphorylated *in vitro* in a c-Src-dependent manner, fractions containing peptides 0 and 3 were isolated by HPLC. Peptide 0 eluted at 8.5% acetonitrile, while peptide 3 eluted at 10.5% acetonitrile (not shown). These HPLC fractions, which were of greater than 95% purity, were subjected to sequential Edman degradation to determine the cycle number at which radioactivity was released. Results from these analyses indicated that a phosphoamino acid residue was located at the second position of peptide 0 (Fig. 4, Panel A) and at the fourth position of peptide 3 (Fig. 4, Panel B). Of the tryptic peptides generated from the intracellular domain of the EGFR which contain Tyr residues, those peptides containing Tyr<sup>845</sup>, Tyr<sup>867</sup>, or Tyr<sup>891</sup> were potential candidates for peptide 0, while those peptides containing Tyr<sup>803</sup> or Tyr<sup>1101</sup> were potential candidates for peptide 3 (see Table I).

TABLE I  
Candidates for peptides 0 and 3

Peptide 0	<b>845</b> Glu-Tyr-His-Ala-Glu-Gly-Lys
	<b>867</b> Ile-Tyr-Thr-His-Gln-Ser-Asp-Val-Trp-Ser-Tyr-Gly-Val-Thr-Val Trp-Glu-Leu-Met-Thr-Phe-Gly-Ser-Lys
	<b>891</b> Pro-Tyr-Asp-Gly-Ile-Pro-Ala-Ser-Glu-Ile-Ser-Ser-Ile-Leu-Glu Lys
Peptide 3	<b>803</b> Gly-Met-Asn-Tyr-Leu-Glu-Asp-Arg
	<b>1101</b> Asp-Pro-His-Tyr-Gln-Asp-Pro-His-Ser-Thr-Ala-Val-Gly-Asn Pro-Glu-Tyr-Leu-Asn-Thr-Val-Gln-Pro-Thr-Cys-Val-Asn-Ser Thr-Phe-Asp-Ser-Pro-Ala-His-Trp-Ala-Gln-Lys

The Tyr<sup>845</sup>-containing peptide was selected for further study as a candidate for peptide 0, since it showed 50% homology to sequences contained within the autophosphorylation site of Src (Tyr<sup>416</sup>), indicating that it could be a potential c-Src target. The octamer composed of E(P-Y<sup>845</sup>)HAEGGK (peptide 0) was chemically synthesized to include a phosphorylated Tyr<sup>845</sup> and analyzed either alone (Fig. 5, Panel A) or in a mixture with total peptides from *in vitro* labeled, c-Src-associated receptor by two-dimensional TLC (Panel C). The synthetic octamer comigrated with peptide 0 in the mixture, thereby identifying Tyr<sup>845</sup> as the phosphorylated residue in peptide 0.

Since peptides 0 and 3 migrated similarly in the two-dimensional chromatography, it was expected that they would share similar isoelectric points and hydrophobicities. Both candidates for peptide 3 (GMNY<sup>803</sup>LEDR or DPHY<sup>1101</sup> QDPHSTAVGNPEYLNTVQPTCVNSTFDSPAHWAKQ, see Table I) had theoretical isoelectric points and calculated hydrophobic indices (22) similar to those of the Tyr<sup>845</sup>-containing peptide, indicating that both were potential candidates. The Tyr<sup>803</sup>-containing peptide was selected first for further study, since it was smaller and more easily synthesized. However, this synthetic phosphopeptide did not co-migrate with peptide 3 nor with any of the other EGFR phosphopeptides (data not shown), indicating that the Tyr<sup>1101</sup>-containing peptide was the preferred candidate. To verify the identity of peptide 3, *in vitro* labeled peptide 3 was scraped off the TLC plate, eluted with pH 1.9 buffer, and subjected to further digestion with a proline-directed protease as described under "Materials and Methods." Since, of the two candidate peptides, only the Tyr<sup>1101</sup>-containing peptide contains proline residues, any change in mobility resulting from digestion with this protease would confirm its identity as peptide 3. As a control, peptide 0, which does not contain any proline residues, was digested with proline-directed protease and no change in mobility was observed (data not shown). Fig. 6 shows that digestion of spot 3 with the proline-directed protease resulted in a change of migration primarily in the first dimension (compare Panel A with Panel B). To confirm that a mobility shift was indeed occurring, digested and undigested peptide 3 were mixed (Panel C). The results identify peptide 3 as Tyr<sup>1101</sup>.

**Phosphorylation of Tyr<sup>845</sup> and Tyr<sup>1101</sup> in HER1 from Breast Tumor Cells**—Our laboratory has previously demonstrated the presence of EGF-dependent c-Src-EGFR heterocomplexes in several human breast tumor cell lines including MDA468, which overexpresses both c-Src and HER1 (16). Since the presence of this heterocomplex is correlated with general increases in downstream receptor-mediated signaling and tumorigenicity in these cells, as compared with cell lines which do not overexpress the EGFR, we wished to investigate whether Tyr<sup>845</sup> and/or Tyr<sup>1101</sup> were phosphorylated in c-Src-associated EGFR derived from breast tumor cells. Fig. 7 demonstrates

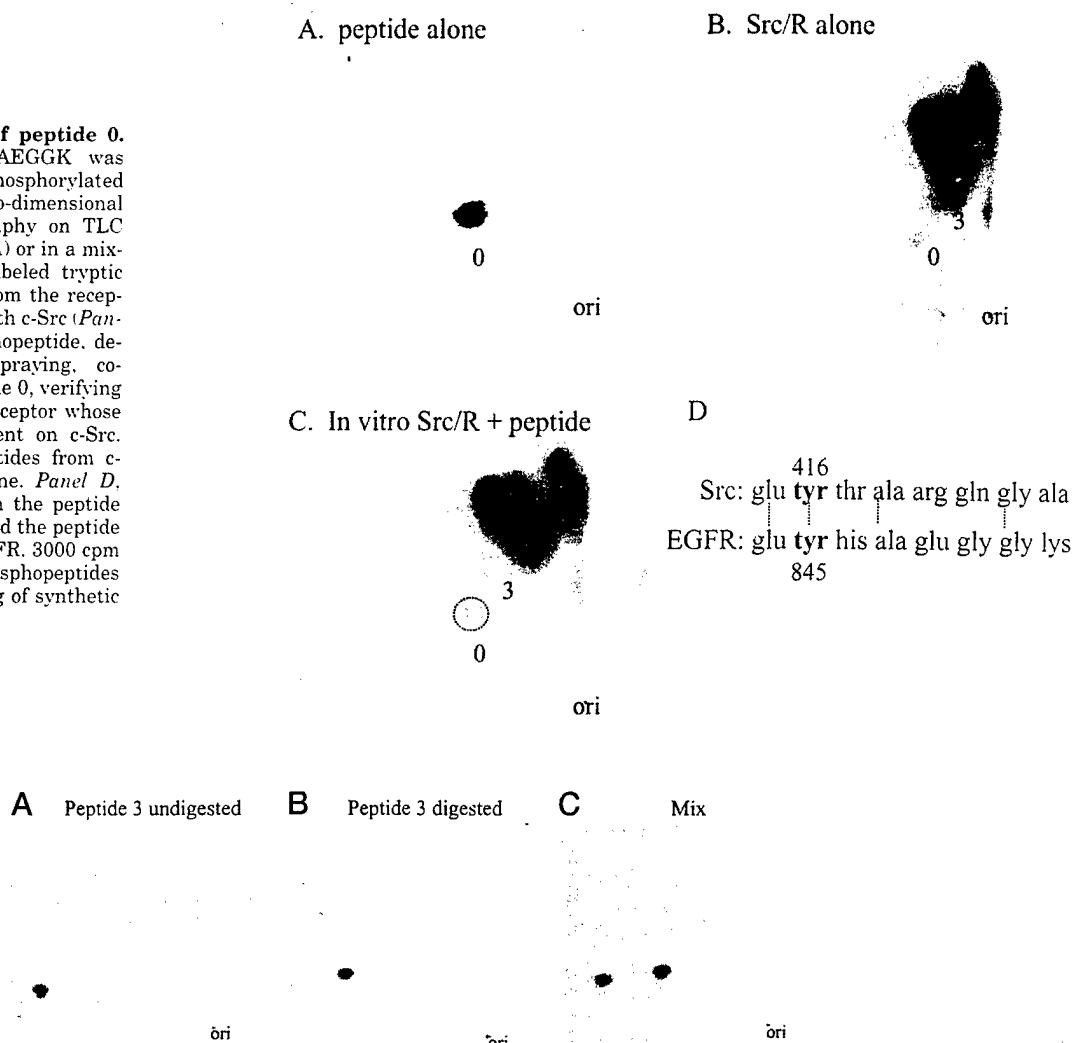

that phosphopeptides 0 and 3 are both present in *in vitro* labeled, c-Src-associated EGFR from EGF-stimulated MDA468 cells, although peptide 0 is weakly detected in the absence of pervanadate treatment. To further investigate the role of c-Src in mediating the phosphorylation of these sites, an MDA468 derivative cell line which stably overexpresses c-Src approximately 25-fold over levels in normal breast epithelial cells (MDA468c-Src cells, Panel B) was created. In these cells, the phosphorylation of peptide 0 (Tyr<sup>845</sup>) was greatly enhanced, while the phosphorylation of peptide 3 (Tyr<sup>1101</sup>) was unchanged (Panel C).

**Role of Tyr<sup>845</sup> in EGF-dependent Mitogenesis**—A tyrosyl residue homologous to Tyr<sup>845</sup> is conserved in many other receptor tyrosine kinases, and mutation of these conserved tyrosines to phenylalanine results in a reduced ability of the receptors to signal downstream events (35–37). Thus, it is possible that mutation of Tyr<sup>845</sup> to phenylalanine would likewise decrease EGF-dependent signaling through the EGFR. To directly test the requirement of Tyr<sup>845</sup> phosphorylation for receptor function, a variant receptor bearing a Y845F mutation was transiently transfected into Neo cells, and the effects on DNA synthesis were assayed by measuring bromodeoxyuridine (BrdUrd) incorporation in response to EGF (Fig. 8). The level of BrdUrd incorporation in cells expressing the Y845F mutant EGFR was reduced to approximately 30% of that induced by the wild type receptor, indicating that the mutant EGFR could interfere with the function of endogenous receptor and was thus acting in a dominant negative manner. Similar results were obtained when Y845F receptor was expressed in cells which overexpress c-Src (38). These findings suggest that phosphorylation of Tyr<sup>845</sup> is necessary for the mitogenic function of the receptor.

## DISCUSSION

Previous studies from our laboratory using the C3H10T1/2 murine fibroblast model demonstrated that simultaneous overexpression of c-Src and EGFR potentiates EGF-dependent mitogenesis, transformation, and tumorigenesis, as well as EGF-dependent association of c-Src with the receptor and increases in tyrosyl phosphorylation of the receptor substrates Shc and PLC $\gamma$  (15). These events correlated with the appearance of two novel tyrosine phosphorylation sites on the receptor, suggesting that one mechanism by which c-Src could synergize with the EGFR is by physically complexing with it and mediating the phosphorylation of novel non-autophosphorylation tyrosine residues, which in turn may result in hyperactivation of the receptor and enhanced phosphorylation of receptor substrates. This increased signaling would then culminate in augmented cell division and tumor growth. Such a model was recapitulated in breast cancer cell lines of epithelial origin, wherein cell lines that express high levels of c-Src and EGFR exhibit EGF-de-

**FIG. 5. Identification of peptide 0.** The octapeptide E(Y-P)HAEGGK was synthesized to contain phosphorylated Tyr<sup>845</sup> and analyzed by two-dimensional electrophoresis/chromatography on TLC plates, either alone (*Panel A*) or in a mixture with total *in vitro* labeled tryptic phosphopeptides derived from the receptor which co-precipitated with c-Src (*Panel C*). The synthetic phosphopeptide, detected by hypochlorite spraying, co-migrated with tryptic peptide 0, verifying Tyr<sup>845</sup> as the site on the receptor whose phosphorylation is dependent on c-Src. *Panel B*, total phosphopeptides from c-Src-associated receptor alone. *Panel D*, sequence homology between the peptide containing Tyr<sup>846</sup> of c-Src and the peptide containing Tyr<sup>845</sup> of the EGFR. 3000 cpm of *in vitro* labeled tryptic phosphopeptides were loaded along with 2 µg of synthetic phosphopeptide.

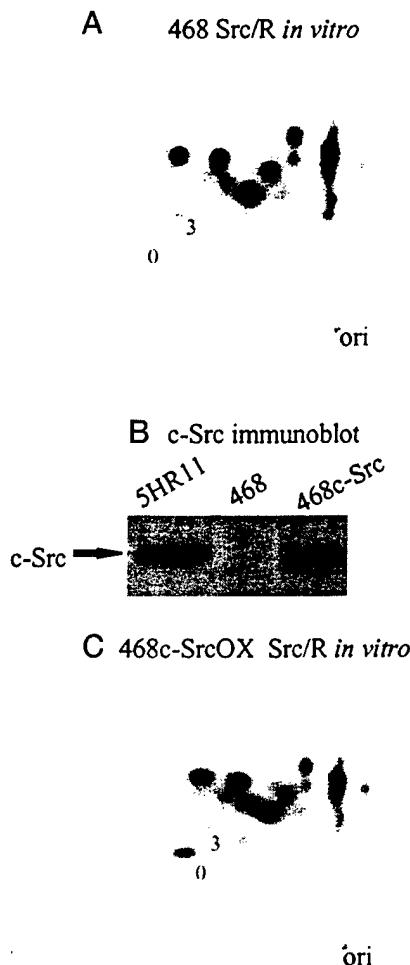

**FIG. 6. Identification of peptide 3.** *In vitro* phosphorylated peptide 3 (as in Fig. 5*B*) was scraped and eluted from the TLC plate and subjected to digestion with proline-directed protease. Undigested or digested, eluted peptide 3 was then analyzed by two-dimensional TLC either alone (*Panels A* and *B*, respectively) or mixed (*Panel C*). The altered mobility of digested peptide 3 indicates the presence of a proline in the sequence and identifies the peptide as containing  $\text{Tyr}^{101}$ . 100 cpm of either digested or undigested peptide 3 were loaded on each TLC plate.

pendent association between c-Src and the receptor, augmented signaling through Shc and MAP kinase, and enhanced tumor formation, as compared with breast tumor cell lines which do not overexpress both c-Src and the EGFR (16). Because these and other studies link c-Src and the EGFR etiologically to tumorigenesis and malignant progression in many human tumors (reviewed in Ref. 12), identification of the two novel c-Src-dependent phosphorylations on the receptor and determination of their functions has taken on added importance, as they represent possible sites for therapeutic intervention.

Here we identify these c-Src dependent sites as Tyr<sup>845</sup> and Tyr<sup>1101</sup> and demonstrate that they become phosphorylated in murine fibroblasts both *in vitro* and *in vivo* in c-Src/EGFR double overexpressing cells in an EGF-dependent manner. Enhanced phosphorylation of Tyr<sup>845</sup> was also observed in MDA468 human breast cancer cells when c-Src was overexpressed, indicating that such phosphorylations can occur in cells of both mesodermal and epithelial origin. More importantly, the fact that cells expressing a Y845F variant of the EGFR are impaired in their ability to synthesize DNA in response to EGF treatment provides direct evidence for the importance of this phosphorylation. Together, these findings support the hypothesis that the c-Src-mediated phosphorylation of Tyr<sup>845</sup> is a critical event for EGFR function, and in certain situ-

ations where overexpression of these molecules exists (such as in certain breast tumors), the increased receptor signaling resulting from this phosphorylation could lead to enhanced tumorigenesis.

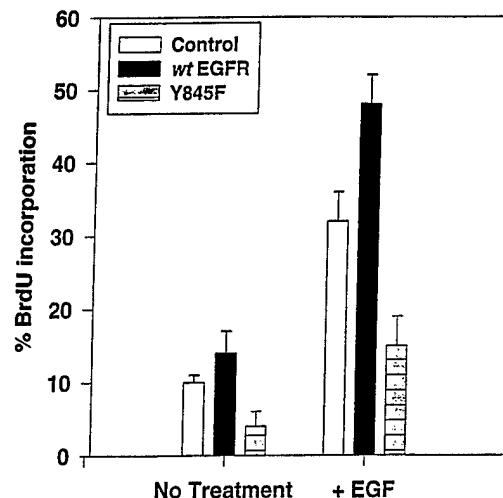

Tyr<sup>845</sup> resides in an intriguing position on the receptor, namely in the activation lip of the kinase domain (39, 40). Amino acid sequences in this lip are highly conserved among tyrosine kinases (41). Crystallographic studies indicate that phosphorylation of Tyr<sup>845</sup> homologues stabilizes the activation lip, maintains the enzyme in an active state, and provides a binding surface for substrate proteins: while mutation of these sites in their respective receptors results in decreases in cell growth and transformation (37, 40–43). A similar situation appears to exist for the EGFR, as cells expressing the Y845F variant receptor showed decreases in their ability to respond mitogenically to EGF. This impairment of DNA synthesis occurred both in a background of endogenous levels of c-Src, as shown here, as well as in cells where c-Src was overexpressed (38). This finding argues that endogenous levels of c-Src are capable of mediating the phosphorylation of Tyr<sup>845</sup> and that the Y845F form of the receptor acts in a dominant negative fashion. Which downstream targets of the receptor are affected in various cell types by the Y845F mutation is not known. Other studies from our laboratory demonstrate that EGF-induced increases in Shc and mitogen-activated protein kinase tyrosyl

**FIG. 7. Phosphorylation of Tyr<sup>845</sup> and Tyr<sup>1101</sup> in MDA468 breast tumor cells.** MDA468 or MDA468c-Src cells were stimulated with 100 ng/ml EGF for 30 min. followed by lysis in CHAPS buffer and immunoprecipitation of extract proteins with either c-Src-specific (GD11) or EGFR-specific (F4) antibody. Precipitated proteins were then subjected to an *in vitro* kinase reaction. The labeled EGFR was eluted from gel slices, and samples were trypsinized and processed as described previously in the legend to Fig. 3. Labeled peptides were visualized by autoradiography. *Panel A*, phosphotryptic peptides from *in vitro* labeled EGFR immunocomplexes from MDA468 cells (4000 cpm). *Panel B*, protein extracts (50 µg) from MDA468 parental, 5HR, or MDA468c-Src cells which overexpress c-Src, were separated by SDS-PAGE and subjected to immunoblotting with GD11 antibody. *Panel C*, phosphotryptic peptides from *in vitro* labeled c-Src-associated EGFR from MDA468c-Src cells (4000 cpm).

phosphorylation occur normally when the Y845F receptor is transiently co-expressed in COS cells (38). This finding suggests that a mitogen-activated protein kinase-independent pathway plays a more dominant role in mitogenic signaling emanating from the receptor when it is phosphorylated on Tyr<sup>845</sup>.

That phosphorylation of this Tyr<sup>845</sup> residue may regulate receptor activity is consistent with the observation that a Tyr<sup>845</sup> homologue is not found in the EGFR family member erbB3/HER3, which is known to lack kinase activity (44). However, unlike the situation resulting from mutation of the analogous site in other receptor tyrosine kinases, mutation of Tyr<sup>845</sup> does not appear to alter the EGF receptor's ability to autophosphorylate or to phosphorylate the downstream substrate, Shc (38). In many tyrosine kinases, including Src, JAK 2, and receptors for colony stimulating factor-1, platelet-derived growth factor, insulin, and fibroblast growth factor, the Tyr<sup>845</sup> homologue is an autophosphorylated residue (35, 36, 45–48). However, to date Tyr<sup>845</sup> has not been identified as an

**FIG. 8. Phosphorylation of Tyr<sup>845</sup> is required for EGF-induced DNA synthesis.** Neo control cells were transfected with plasmid DNA encoding Y845F or wild type EGFR, cultured for 2 days, serum starved for 30 h, and left untreated or treated with 40 ng/ml EGF for an additional 18 h. Cells were fixed and co-stained for EGFR expression and BrdUrd incorporation. Results are expressed as the mean percent ± S.E. of cells expressing EGFR that were positive for BrdUrd incorporation. Thirty-five to 75 cells were analyzed for each variable in three independent experiments.

autophosphorylation site for the EGF receptor. This could be due to the highly labile nature of the phosphorylation and/or to the fact that c-Src appears to regulate its phosphorylation (see Figs. 2, 3, and 7). Together these findings raise a number of questions: namely, whether c-Src phosphorylates Tyr<sup>845</sup> directly, whether binding of c-Src to the receptor causes the receptor to phosphorylate itself, or whether another tyrosine kinase which mediates the phosphorylation is recruited into the complex or activated by c-Src.

Several pieces of evidence support the hypothesis that c-Src phosphorylates the receptor directly. First, Tyr<sup>845</sup> is homologous to Tyr<sup>416</sup> in Src, which is an autophosphorylation site for Src (39). Additional evidence comes from our studies with both 10T1/2 murine fibroblasts and MDA468 breast cancer cells overexpressing c-Src, where an enhanced phosphorylation of Tyr<sup>845</sup> is observed. Moreover, other studies from our laboratory demonstrate that overexpression of a kinase inactive form of c-Src in 10T1/2 cells or in MDA468 cells results in a striking decrease in Tyr<sup>845</sup> phosphorylation (38).<sup>4</sup> These latter findings indicate that c-Src kinase activity is necessary for the phosphorylation of Tyr<sup>845</sup> and strongly argue that Tyr<sup>845</sup> is a direct substrate of c-Src. Last, *in vitro* affinity precipitation and Far Western analyses (Fig. 1, this report, and Refs. 29, 49, and 50) demonstrate that the c-Src SH2 domain can bind activated EGFR specifically and directly, suggesting that recruitment of other tyrosine kinases is not necessary to mediate the phosphorylation of Tyr<sup>845</sup>. However, other EGFR family members (including HER2/neu) (2, 51, 52) and several cytosolic tyrosine kinases, such as other c-Src family members (13) and JAK kinases (53, 54), have been reported to be involved in receptor-mediated signaling, and we cannot exclude their possible involvement in phosphorylation of Tyr<sup>845</sup> or of Tyr<sup>1101</sup>. Whether simple binding of c-Src induces a conformational change in the receptor so that it can autophosphorylate is a much more difficult question to address, a question that minimally awaits identification of the c-Src-binding site.

Other investigators have also described Src-mediated phosphorylations on the EGFR, and Wasilenko *et al.* (24) demon-

<sup>4</sup> J. S. Biscardi and D. A. Tice, unpublished results.

strated that in NIH3T3 cells co-expressing the transforming oncoprotein v-Src along with EGFR, the receptor contained several novel sites of tyrosine phosphorylation, one of which they postulated might be Tyr<sup>845</sup> (SPY1). Sato *et al.* (55) provide additional evidence for phosphorylation of Tyr<sup>845</sup> in A431 cells in a c-Src-dependent fashion, while Stover *et al.* (56) showed that Tyr<sup>891</sup> and Tyr<sup>920</sup> were phosphorylated in the c-Src-associated EGFR derived from MCF7 cells. However, neither we nor Sato *et al.* (55) have been able to detect phosphorylation of Tyr<sup>891</sup> or Tyr<sup>920</sup>, and none of these reports have linked the various phosphorylations to biological changes in receptor activity (e.g. mitogenesis, tumorigenesis). Thus, while there is some discrepancy among the different cell systems, our data and those of others indicate that Tyr<sup>845</sup> is a major c-Src-dependent phosphorylation site on the EGFR, and that it is associated with increases in receptor function. These findings suggest that multiple tyrosine phosphorylations may be regulated by c-Src.

A potential role for Tyr<sup>1101</sup> is more unclear, as this residue is not conserved among EGFR family members and its phosphorylation level *in vivo* is not as noticeably altered upon c-Src overexpression as is that of Tyr<sup>845</sup> (see Fig. 3). However, Tyr<sup>1101</sup> may function as a docking site for novel or known signaling proteins, perhaps in an SH2-dependent manner similar to that of the other autophosphorylation sites in the COOH terminus. One of the candidate binding proteins is c-Src itself. In peptide inhibition experiments using synthetic peptides to inhibit the binding between the EGFR and the SH2 domain of c-Src, the SH2 domain of c-Src was shown to bind Tyr<sup>992</sup> (49, 55) and Tyr<sup>1101</sup> (50) preferentially. Thus, c-Src could bind one of these sites, which could position it to phosphorylate Tyr<sup>845</sup>. In MDA468 breast cancer cells, Tyr<sup>845</sup> appeared to be the site most affected by c-Src. While the data from the 10T1/2 system suggests that the phosphorylation of both Tyr<sup>1101</sup> and Tyr<sup>845</sup> is dependent on c-Src, it may be that the phosphorylation of each peptide turns over at different rates in different cell types. Also, the endogenous levels of c-Src in the parental MDA468 cells may be capable of phosphorylating Tyr<sup>1101</sup> to a maximal extent, and no further phosphorylation could result from overexpression. In this regard, overexpression of c-Src may allow for maximal phosphorylation of Tyr<sup>845</sup> if this phosphorylation turns over at a faster rate, which appears to be the case as the results from Fig. 4 indicate.

Our data show that phosphorylation on Tyr<sup>845</sup> appears to be critical for EGFR-mediated mitogenesis. Moreover, our results (Figs. 3 and 7) suggest that basal levels of c-Src are able to mediate phosphorylation of Tyr<sup>845</sup> to some extent, and that this phosphorylation is important to receptor function. In a cell where overexpression and/or activation of c-Src has occurred, as is found in breast cancer, the proper negative regulation of this phosphorylation may be lost, resulting in the increased EGFR-dependent signaling and tumorigenicity. We speculate that c-Src and EGFR act synergistically (via phosphorylation of the receptor by c-Src) to induce enhanced signaling in cells which overexpress both these kinases.

**Acknowledgments**—We thank Drs. John Shannon and Jay Fox of the Biomolecular Research Facility for Edman analysis, synthetic peptide production, and helpful advice in identification of peptide 3; Dr. Michael Weber for directing us toward comparisons of peptide 0 and "SPY1," and members of the Parsons-Weber-Parsons research group for critical discussion.

# Mechanism of biological synergy between cellular Src and epidermal growth factor receptor

DAVID A. TICE, JACQUELINE S. BISCARDI, AMANDA L. NICKLES, AND SARAH J. PARSONS\*

**ABSTRACT** Overexpression of both cellular Src (c-Src) and the epidermal growth factor receptor (EGFR) occurs in many of the same human tumors, suggesting that they may functionally interact and contribute to the progression of cancer. Indeed, in murine fibroblasts, overexpression of c-Src has been shown to potentiate the mitogenic and tumorigenic capacity of the overexpressed EGFR. Potentiation correlated with the ability of c-Src to physically associate with the activated EGFR and the appearance of two unique *in vivo* phosphorylations on the receptor (Tyr-845 and Tyr-1101). Using stable cell lines of C3H10T½ murine fibroblasts that contain kinase-deficient (K-) c-Src and overexpressed wild-type EGFR, we show that the kinase activity of c-Src is required for both the biological synergy with the receptor and the phosphorylations on the receptor, but not for the association of c-Src with the receptor. In transient transfection assays, not only epidermal growth factor but also serum- and lysophosphatidic acid-induced DNA synthesis was ablated in a dominant-negative fashion by a Y845F mutant of the EGFR, indicating that c-Src-induced phosphorylation of Y845 is critical for the mitogenic response to both the EGFR and a G protein-coupled receptor (lysophosphatidic acid receptor). Unexpectedly, the Y845F mutant EGFR was found to retain its full kinase activity and its ability to activate the adapter protein SHC and extracellular signal-regulated kinase ERK2 in response to EGF, demonstrating that the mitogenic pathway involving phosphorylation of Y845 is independent of ERK2-activation. The application of these findings to the development of novel therapeutics for human cancers that overexpress c-Src and EGFR is discussed.

Considerable evidence has accumulated in recent years to suggest that cellular Src (c-Src) and members of the epidermal growth factor (EGF) receptor (EGFR) family are critical elements in the etiology of multiple human cancers. Both kinases are found overexpressed in many of the same types of tumors, including glioblastomas and carcinomas of the colon, breast, and lung (1–4), raising the question of whether they functionally interact to promote the growth of these malignancies. In breast cancer, overexpression of EGFR family members is estimated to occur in 60% or more of the cases (5), and overexpression of the family member HER2/NEU, has been associated with a poor prognosis for the disease (6). Recent reports have also described overexpression of c-Src in a significant majority of patients with breast cancer, a frequency that approaches 100% (1). Studies to assess the oncogenic potential of each kinase have shown that the EGFR is tumorigenic when overexpressed in cultured fibroblasts and activated by ligand (7, 8), but overexpression of c-Src alone is insufficient for malignant transformation (9, 10).

A possible role for c-Src in tumorigenesis was revealed when it was demonstrated in C3H10T½ murine fibroblasts that

co-overexpression of c-Src and the EGFR resulted in a synergistic increase in EGF-induced DNA synthesis, growth in soft agar, and tumorigenesis, as compared with cells overexpressing either the EGFR or c-Src alone (11). This cooperation correlated with the EGF-dependent formation of a physical complex between c-Src and the EGFR (11), the appearance of two unique sites of tyrosine phosphorylation (Y845 and Y1101) on the c-Src-associated EGFR, and increased phosphorylation of receptor substrates (11). These results suggest that one mechanism by which c-Src could augment the mitogenic/tumorigenic activity of the receptor is by associating with and hyperactivating the receptor by phosphorylation of novel tyrosine residues. Co-overexpression, co-association, and phosphorylation of Y845 and Y1101 have also been observed in human tumor cells (12–15), suggesting that synergism between c-Src and the EGFR may occur in a subset of human tumors as well as in murine fibroblasts.

To determine whether phosphorylation of Y845 or Y1101 is critical to the biological synergy between c-Src and the EGFR and to determine whether c-Src is responsible for mediating the phosphorylations, we analyzed a panel of murine fibroblasts that overexpressed either wild-type (wt) c-Src (K+ c-Src) or kinase-defective c-Src (K- c-Src) alone or together with the EGFR for growth properties and the presence of a stable complex containing the EGFR and c-Src. We found that K- c-Src inhibits EGF-dependent growth in soft agar and tumorigenesis in nude mice even though it is still capable of associating with the receptor. However, K- c-Src was unable to mediate the phosphorylation of Y845 on the receptor. As a direct test of the requirement of this phosphorylation for receptor function, we engineered a variant receptor harboring a Y845F mutation in the EGFR and observed that this mutated receptor ablated EGF, serum, and lysophosphatidic acid (LPA)-induced DNA synthesis without inhibiting receptor kinase activity or activation of the extracellular signal-regulated kinase ERK2. The data support a model wherein phosphorylation of Y845 on the EGFR by c-Src is required for EGF-induced mitogenesis and tumorigenesis in a manner that appears to be independent of ERK2.

## MATERIALS AND METHODS

**Cell Lines.** The derivation, characterization, and maintenance of the clonal C3H10T½ murine fibroblast cell lines Neo (control), K+ (wt chicken c-Src overexpressors), K- (A430V kinase-deficient, chicken c-Src overexpressors), EGFR (wt human EGFR overexpressors), and EGFR/K+ (wt EGFR/wt c-Src double overexpressors) have been described previously (10, 11, 16). EGFR/K- (wt EGFR overexpressors/kinase-

This paper was submitted directly (Track II) to the Proceedings office. Abbreviations: c-Src, cellular Src; EGF, epidermal growth factor; EGFR, EGF receptor; K+, wild-type c-Src; K-, kinase-deficient c-Src; wt, wild-type; LPA, lysophosphatidic acid; BrdUrd, 5-bromodeoxyuridine; HA, hemagglutinin; MAPK, mitogen-activated protein kinase; GPCR, G protein-coupled receptor.

'deficient c-Src) cell lines were derived by infection of K<sup>-</sup> cells with a recombinant amphotropic retrovirus encoding the human EGFR (8), cloning by limiting dilution, and screening for overexpression of the receptor and maintenance of K<sup>-</sup> c-Src by Western immunoblotting. Clonal cell lines used in this study were estimated to express 25,000–60,000 human EGFRs per cell, based on comparative Western blotting analysis that used as a standard a C3H10T½ cell line that by Scatchard analysis was shown to express approximately 200,000 receptors per cell (5HR11 cells) (11). Clones included EGFR<sub>5</sub>, EGFR<sub>8</sub>, EGFR<sub>27</sub>, EGFR/K<sup>+</sup><sub>8</sub>, EGFR/K<sup>+</sup><sub>9</sub>, EGFR/K<sup>+</sup><sub>10</sub>, and EGFR/K<sup>-</sup><sub>2</sub>, EGFR/K<sup>-</sup><sub>5</sub>, EGFR/K<sup>-</sup><sub>41</sub>, and EGFR/K<sup>-</sup><sub>56</sub>. K<sup>+</sup> and K<sup>-</sup> c-Src overexpression was estimated to be 20- to 25-fold over endogenous.

**Western Immunoblotting.** Western blot analysis was performed as previously described (11, 16), using Ab-4 rabbit polyclonal antibody (Calbiochem) or F-4 mouse monoclonal antibody (mAb)(Sigma) to detect the EGFR, purified 2–17 mAb (Quality Biologicals; Gaithersburg, MD) or EC10 ascites fluid mAb (prepared in our laboratory and used at a 1:10,000 dilution) to identify c-Src, polyclonal anti-SHC antibody (Upstate Biotechnology; Lake Placid, NY) to visualize SHC, B3B9 mAb (17) to detect MAPK, polyclonal anti-phospho-MAPK antibody (Promega), or 4G10 anti-phosphotyrosine antibody (Upstate Biotechnology) to detect tyrosine-phosphorylated SHC. <sup>125</sup>I-labeled protein A (ICN) or <sup>125</sup>I-labeled goat anti-mouse or anti-rabbit Ig (New England Nuclear) and autoradiography were employed to localize binding of primary antibodies.

**Colony Formation in Soft Agar and Tumorigenicity.** Anchorage-independent growth was measured as previously described (11). Colonies were stained for 20 hr at 37°C in a solution of iodonitrotetrazolium violet (1 µg/ml; Sigma) in water and counted by using EAGLESIGHT analysis software (Stratagene). The soft agar colony data include analysis of three separate clones for each cell type. EGFR<sub>5</sub>, EGFR<sub>8</sub>, EGFR<sub>27</sub>, EGFR/K<sup>+</sup><sub>8</sub>, EGFR/K<sup>+</sup><sub>9</sub>, EGFR/K<sup>+</sup><sub>10</sub>, EGFR/K<sup>-</sup><sub>2</sub>, EGFR/K<sup>-</sup><sub>5</sub>, and EGFR/K<sup>-</sup><sub>56</sub>. Assessment of tumor formation in Taconic *nu/nu* mice was performed as previously described (11).

**In Vitro Kinase Assay, Metabolic Labeling with <sup>32</sup>P<sub>i</sub>, and Two-Dimensional Tryptic Phosphopeptide Analysis.** Methods for immunoprecipitation, *in vitro* kinase assay, metabolic <sup>32</sup>P<sub>i</sub> labeling, and two-dimensional phosphopeptide analysis have been described (11, 15). In the metabolic labeling experiments, 5 µM pervanadate and 3 mM H<sub>2</sub>O<sub>2</sub> were added to cells simultaneously with 100 ng/ml EGF and incubated for 5 min before harvesting.

**S-Bromodeoxyuridine (BrdUrd) Incorporation.** A pcDNA3 vector (Invitrogen) encoding human EGFR with a Y845F mutation was constructed by inserting a *Dra*III-*Bst*EII fragment containing the Y845F mutation (from plasmid pCO11, gift of L. Beguinot, Laboratory of Molecular Oncology, Milan, Italy) into the corresponding *Dra*III-*Bst*EII site of pcDNA3 encoding wt EGFR (gift of S. Decker, Parke-Davis, Ann Arbor, MI). K<sup>+</sup> cells were transiently transfected with 4 µg of vector, wt EGFR, or Y845F EGFR plasmid DNA by using 30 µg of Superfect (Qiagen; Chatsworth, CA) according to manufacturer's directions and incubated in a humidified, 37°C, 5% CO<sub>2</sub>/95% air atmosphere for 48 hr to allow a confluent monolayer to form. Transfected cells were then serum-starved for 30 hr prior to addition of 100 µM BrdUrd and 40 ng/ml EGF, 10% fetal bovine serum (FBS) in growth medium, or 10 µM LPA, at which time they were incubated for an additional 18 hr and costained for human EGFR expression and BrdUrd incorporation as described by the manufacturer of the BrdUrd-specific mAb (Boehringer Mannheim). Specifically, fixed cells were treated with 2 M HCl for 1 hr at 37°C and incubated with a mixture of primary antibodies (1:100 dilution of EGFR-specific Ab-4 and a 1:15 dilution of anti-BrdUrd mAb).

followed by incubation with a mixture of secondary antibodies (75 µg/ml fluorescein isothiocyanate-conjugated goat anti-rabbit IgG and 4 µg/ml Texas red-conjugated goat anti-mouse IgG, both from Jackson ImmunoResearch).

**Transient Transfections.** COS-7 cells were transiently transfected with plasmids encoding SHC and ERK2, by using Superfect as described above. HA-SHC (gift of K. Ravichandran; Univ. of Virginia; HA indicates influenza virus hemagglutinin) or Flag-ERK2 (gift of M. Weber; Univ. of Virginia) was transfected at a 1:5 ratio with or without either wt EGFR or Y845F mutant EGFR and incubated in a humidified, 37°C,

5% CO<sub>2</sub>/95% air atmosphere for 48 hr to allow a confluent monolayer to form. Transfected cells were then serum-starved overnight and either stimulated with 100 ng/ml EGF for 10 min or left untreated. Extracts were immunoprecipitated with either 12CA5 anti-HA antibody (Babco: Richmond, CA) or anti-Flag M2 affinity gel (Kodak) and resolved by SDS/PAGE.

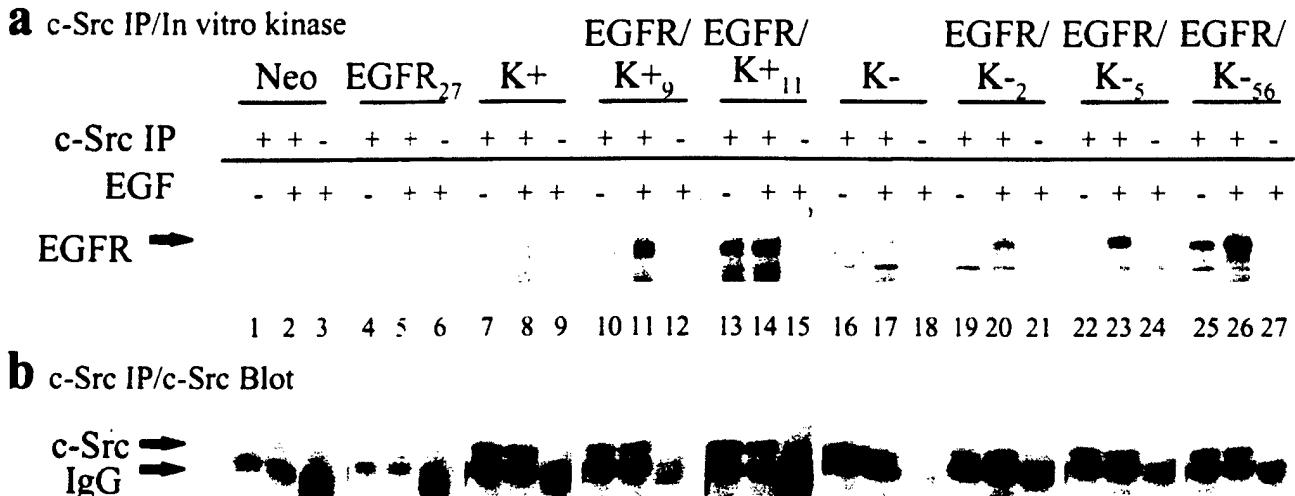

## RESULTS AND DISCUSSION

To determine whether phosphorylation of Y845 or Y1101 was dependent on c-Src catalytic activity, clonal C3H10T½ fibroblasts that stably overexpress wt EGFR and K<sup>-</sup> chicken c-Src were created from a stable K<sup>-</sup> c-Src expressing line, as described in *Materials and Methods*. Fig. 1a shows the levels of receptor and c-Src that are expressed in the various cell lines used in this study. EGFR/K<sup>-</sup> clones (lanes 6–8) expressed levels of receptor comparable to those in EGFR/K<sup>+</sup> (lane 4) and EGFR (lane 2) lines, whereas all clones expressing K<sup>-</sup> c-Src (lanes 5–8) contained amounts of c-Src comparable to those of clones expressing K<sup>+</sup> c-Src (lanes 3 and 4). Fig. 1b shows that the EGFR/K<sup>-</sup> clones exhibited diminished anchorage-independent growth in the presence of EGF compared with EGFR/K<sup>+</sup> double overexpressors, demonstrating a requirement for the kinase activity of c-Src for potentiation of EGF-induced soft agar growth. Moreover, relative to cells overexpressing EGFR alone, the EGFR/K<sup>-</sup> clones also showed reduced soft agar growth, indicating that K<sup>-</sup> c-Src can function in a dominant-negative fashion for EGFR-induced colony formation. The dominant-negative effect was manifested by both reduced number (Fig. 1b) and significantly smaller average size (Fig. 1c) of the EGFR/K<sup>-</sup> colonies as compared with those of EGFR/K<sup>+</sup> or EGFR cells. As pre-

viously reported, Neo control and K<sup>+</sup> c-Src cells produced no or significantly fewer colonies than EGFR cells (11). K<sup>-</sup> c-Src cells also gave no colonies (data not shown). Table 1 shows that the growth of tumors *in vivo* was completely ablated in mice injected with EGFR/K<sup>-</sup> cells compared with EGFR or EGFR/K<sup>+</sup> cells, demonstrating that K<sup>-</sup> c-Src has an even stronger dominant-negative effect on tumor growth *in vivo* than on growth in soft agar. Together these results underline the requirement for c-Src kinase activity in both the potentiating effect of overexpressed wt c-Src and the ability of overexpressed EGFR alone to induce oncogenic growth.

To determine whether K<sup>-</sup> c-Src might be eliciting its biological effects through the receptor, we examined the association between the two kinases, using an immune complex *in vitro* kinase assay as previously described (11). c-Src was immunoprecipitated from the C3H10T½ clones with a chicken c-Src-specific antibody, EC10, to minimize recognition of endogenous c-Src and to determine whether the exogenously expressed K<sup>-</sup> c-Src could interact with the EGFR. An EGF-sensitive *in vitro* phosphorylation of an ≈170-kDa protein was observed in the c-Src immunoprecipitates prepared from EGFR/K<sup>-</sup> (Fig. 2a, lanes 20, 23, and 26) as well as from EGFR/K<sup>+</sup> cells (lanes 11 and 14). These results demonstrate that c-Src kinase activity is not required for association and suggest that K<sup>-</sup> c-Src may be eliciting its dominant negative effects (at least in part) directly through the receptor, since the association is still intact.

As described before (11), two tryptic phosphopeptides appear in the map of *in vitro* phosphorylated receptor associated with K<sup>+</sup> c-Src (Fig. 3B) that are either absent or present in reduced amounts in the map of "free" activated receptor (Fig. 3A). These peptides contain Y845 and Y1101, whose identification is described in ref. 15. In contrast to the receptor associated with K<sup>+</sup> c-Src, phosphorylation of Y845 was undetectable in receptor associated with K<sup>-</sup> c-Src (Fig. 3C and D), while the level of Y1101 phosphorylation was visible but reduced. Similar results were observed in <sup>32</sup>P metabolic labeling experiments (Fig. 3E and F). Phosphorylation on Y845 was also observed in cells expressing endogenous levels of c-Src, but only after treatment with pervanadate (15), suggesting that this site is phosphorylated in the absence of overexpression of c-Src and that it is rapidly turned over. These results indicate that phosphorylation of Y845, and to a lesser

**FIG. 2.** K<sup>-</sup> c-Src associates with the EGFR. Confluent, serum-starved cells were untreated or treated with EGF (100 ng/ml) for 15 min, and extracts were immunoprecipitated with either chicken c-Src-specific mAb EC10 (designated +) or a negative control mouse IgG (−). (a) Immunocomplexes were subjected to an *in vitro* kinase assay using [ $\gamma$ -<sup>32</sup>P]ATP, and phosphorylated products were analyzed by SDS/PAGE and autoradiography. The region of the autoradiograph around the 170-kDa products is shown. (b) The amount of c-Src in each precipitate was visualized by Western immunoblot analysis with EC10 mAb. K<sup>-</sup> c-Src in EGFR/K<sup>-</sup> clones was verified to be catalytically inactive in the immune complex kinase assay (data not shown).

extent of Y1101, depends on the kinase activity of c-Src, both *in vitro* and *in vivo*.

The position corresponding to Y845 is highly conserved among serine/threonine and tyrosine kinases and is situated in the activation loop between subdomains VII and VIII (18). Three-dimensional structural studies of several kinases have pointed to the importance of phosphorylation of this residue in stabilizing the activation loop in a conformation favorable for substrate and ATP binding (19–21). In agreement with the structural data, mutational analysis of the corresponding residue in tyrosine kinase receptors, including p185<sup>neu</sup>, a highly conserved family member, has shown a requirement for phosphorylation of this residue for full biological function in response to ligand (22–27). Y845 homologues in other tyrosine kinase receptors have all been shown to be autophosphorylation sites. In contrast, Y845 of the EGFR has not been identified as such, and its importance to EGFR function has not been ascertained. The failure to identify Y845 as a site of autophosphorylation may reflect either the highly labile nature of the phosphorylation or the c-Src dependency of the phosphorylation (15, 28).

To determine whether phosphorylation of Y845 is required for receptor kinase activity, we compared wt EGFR autokinase activity with that of a mutant Y845F EGFR. Similar amounts of autophosphorylation were observed in an *in vitro* kinase assay of Y845F or wt EGFR immunoprecipitated from transiently transfected and EGF-stimulated COS-7 cells (Fig. 4). Further evidence that the EGFR, unphosphorylated on

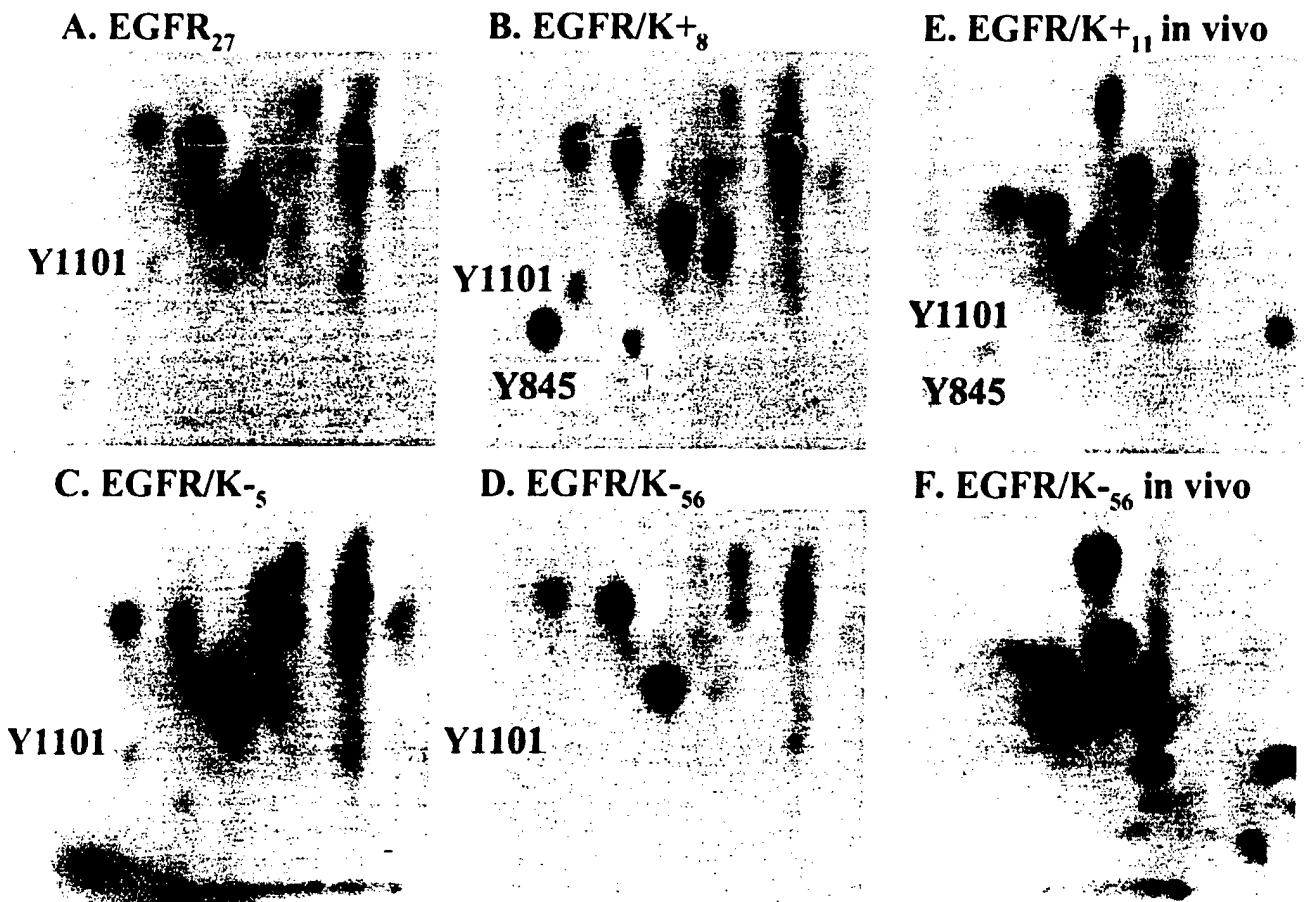

FIG. 3. Y845 is not phosphorylated in EGFR complexed with K<sup>−</sup> c-Src. (A–D) The 170-kDa bands that were phosphorylated *in vitro* (as in Fig. 2) in c-Src (B–D) or receptor (A) immunocomplexes prepared from the indicated cell lines were excised, digested with trypsin, resolved by two-dimensional electrophoresis/chromatography, and subjected to autoradiography. The positions of peptides containing Y845 and Y1101, which were identified previously (15), are indicated. (E and F) Receptor immunoprecipitates from the indicated cell lines that had been metabolically labeled with <sup>32</sup>P were analyzed as in A–D. Equal cpm were loaded in A–D and in E vs. F. The apparent increase in tyrosine phosphorylation in F is due to a slightly darker exposure compared with E to emphasize the complete ablation of Y845 phosphorylation. The appearance of darker or novel spots in F was not reproduced in repeated experiments.

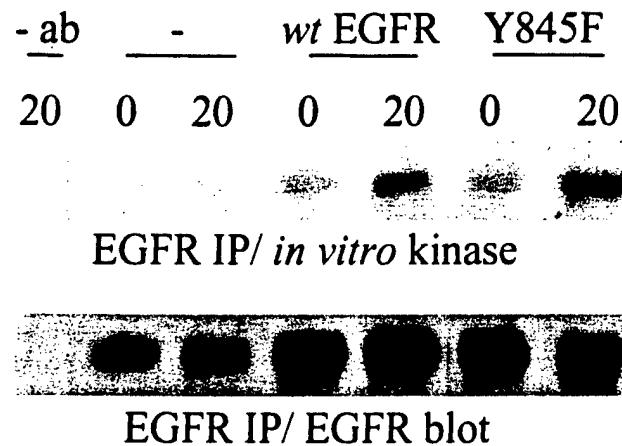

FIG. 4. Phosphorylation of Y845 is not essential for EGFR autokinase activity. COS-7 cells were transiently transfected with either vector alone (−), or plasmids encoding Y845F or wt EGFR and stimulated with EGF for 5 min. The EGFR was immunoprecipitated from extracts and subjected to an *in vitro* kinase assay for 0 or 20 min. The reaction was stopped with the addition of sample buffer, and the products were resolved by SDS/PAGE and transferred to a membrane. After autoradiography, EGFR was detected by Western immunoblotting and visualized by using enhanced chemiluminescence (ECL; Amersham).

Y845F retains its ability to autophosphorylate is provided by a comparison of the tryptic phosphopeptide maps of wt EGFR from EGFR cells (Fig. 3A) and wt EGFR from EGFR/K<sup>−</sup> cells

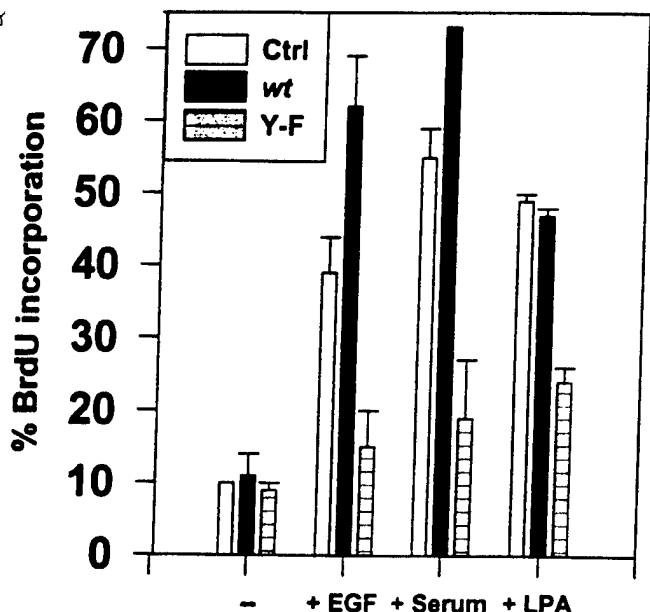

FIG. 5. Phosphorylation of Y845 is essential for EGFR function. K<sup>+</sup> cells were transfected with plasmid DNA encoding Y845F (Y-F) or wt EGFR, cultured for 2 days, serum starved for 30 hr, and left untreated or treated with 40 ng/ml EGF, 10% fetal bovine serum, or 10 μM LPA for 18 hr. Results are expressed as the mean percent ± SEM of cells expressing EGFR that were positive for BrdUrd incorporation. Thirty-five to 100 cells were analyzed for each variable in three independent experiments.

(Fig. 3 C and D), where in the latter instance, autophosphorylation is maintained in the absence of detectable Y845 phosphorylation. These data suggest that, unlike other receptor tyrosine kinases mutated at the Y845 homologue, the Y845 mutant EGFR maintains its ability to autophosphorylate.

To test whether phosphorylation on Y845 is important for the mitogenic function of the EGFR independent of its autokinase activity, we transiently transfected a Y845F mutant or wt receptor into K<sup>+</sup> cells and assessed mitogenesis by measuring EGF-induced BrdUrd incorporation into newly synthesized DNA. In contrast to the wt receptor, the Y845F mutant was unable to stimulate DNA synthesis upon EGF treatment (Fig. 5). Indeed, the reduced level of BrdUrd incorporation, which approached that of serum-starved cells, indicated that Y845F EGFR is capable of interfering with signaling through endogenous receptors, thereby acting in a dominant-negative fashion. These data support the hypothesis that phosphorylation of Y845 is required for the EGF-induced mitogenic function of the receptor.

Surprisingly, the Y845F variant of the EGFR also inhibited serum-induced DNA synthesis in a dominant-negative manner (Fig. 5). The mechanism of this inhibition is unclear at the present time. However, the EGFR has recently been shown to play an essential role in signaling and growth stimulation through G protein-coupled receptors (GPCR) (29), and the Src family of tyrosine kinases has also been directly implicated in GPCR-mediated mitogen-activated protein kinase (MAPK) activation (30, 31). c-Src is thought to be responsible for phosphorylating the EGFR in response to GPCR activation (32), leading to the generation of docking sites. The major mitogenic component of serum is LPA, a ligand for GPCR (33). Therefore, one possible mechanism by which the Y845F EGFR could prevent serum-induced BrdUrd incorporation might be the inability to phosphorylate Y845 via a GPCR route. Indeed, Y845F mutant EGFR was able to reduce (but not ablate) induction of DNA synthesis by LPA, demonstrating an involvement of EGFR signaling in the GPCR pathway (Fig. 5).

Because the EGFR is known to signal to MAPK via a SHC-Grb2-SOS-Ras pathway upon both EGF and G protein stimulation, we also tested the ability of the mutant EGFR to

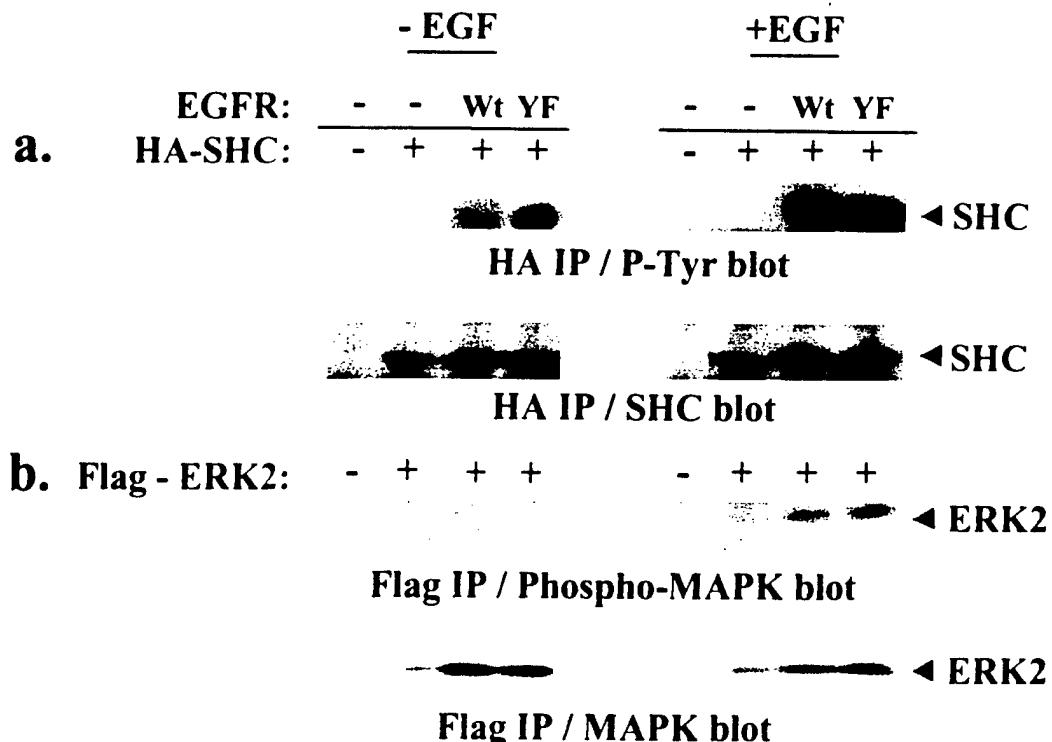

FIG. 6. Y845F mutant receptor retains its ability to phosphorylate SHC and activate MAPK. COS-7 cells were transfected with plasmid DNA encoding HA-SHC or Flag-ERK2 and either Y845F or wt EGFR, cultured for 2 days, serum starved overnight, and left untreated or treated with 100 ng/ml EGF for 10 min. Extracts were immunoprecipitated with 12CA5 anti-HA antibody or anti-Flag M2 affinity gel and resolved by SDS/PAGE. The amount of tyrosine phosphorylated HA-SHC (a) and Flag-ERK2 (b) was observed by Western immunoblot analysis. The amount of wt EGFR or Y845F EGFR expressed in the populations of cells was the same as that shown for Fig. 4.

phosphorylate the direct substrate SHC and to activate ERK2. The presence of the Y845F mutation in the EGFR did not alter the EGF-induced increase in tyrosine phosphorylation of cotransfected SHC or ERK2, compared with wt EGFR (Fig. 6). Minor differences in the relative phosphorylations of either SHC or ERK2 between mutant and wt EGFR were not significant when multiple experiments were quantitated (data not shown). These results suggest that the EGFR stimulates mitogenesis through an ERK2-independent pathway.

The data presented here provide a mechanism for c-Src's role in EGF- and GPCR-mediated DNA synthesis and tumorigenesis. We propose that phosphorylation of Y845 on the EGFR by a c-Src-mediated event is required for EGF- and LPA-induced DNA synthesis. On the basis of the findings that Y845 is not phosphorylated by the wt receptor alone (Fig. 3) and that the kinase activity of c-Src is required for phosphorylation of Y845, we conclude that c-Src is the most likely kinase to phosphorylate the receptor. Interruption of this phosphorylation by overexpressing a kinase-deficient c-Src or a Y845F mutant of the EGFR blocks signaling and thus growth. Furthermore, the block of DNA synthesis by Y845F mutant EGFR is not dependent on its ability to autophosphorylate or to signal to MAPK, suggesting a mechanism of activation in which the activation loop tyrosine does not need to be phosphorylated for kinase activity, but is required for stimulation of a mitogenic pathway not involving ERK2.

These findings have direct implications for the etiology of human cancers. In tumor cells that overexpress both c-Src and the EGF receptor, we postulate that the probability of Y845 phosphorylation increases, an event that results in promotion of growth and anchorage independence. Since phosphorylation of Y845 has been shown to occur in cultured human tumor cells that overexpress c-Src (15), the above paradigm may have relevance for the disease *in situ*. Development of methods to inhibit the ability of c-Src to phosphorylate Y845 may result in a novel, more "tumor-specific" treatment for cancers such as carcinomas of the colon, breast, and lung.

We thank Drs. S. Decker and L. Beguinot for wt and Y845F EGFR cDNA, respectively. D. Lowy and his lab for retroviral stocks, and members of the S.J.P. lab and the Parsons-Weber-Parsons group for helpful discussions. This work was supported by research grants CA71449 and CA39438 from the National Cancer Institute and 4621 from the Council for Tobacco Research (S.J.P.), a graduate fellowship (DAMD 17-96-6126) (D.A.T.), and a postdoctoral fellowship (DAMD 17-97-7329) (J.S.B.), both from the Department of Defense.

Apoptosis

## ABSTRACT

Evidence from a murine fibroblast model and human breast cancer cells indicates that c-Src and the human EGF receptor (HER1) synergize to enhance neoplastic transformation and progression of mammary epithelial cells. To investigate whether interactions between c-Src and other HER family members may also play a role in breast tumor progression, we characterized a panel of thirteen human breast carcinoma cell lines and thirteen tumor samples for expression levels of HER family members and c-Src and examined a subset of the cell lines for their dependency on Src family members for heregulin (HRG)-augmented, anchorage-dependent growth in reduced serum or colony formation in soft agar. By Western immunoblotting, we found that (1) all cell lines overexpressed one or more HER family member, (2) ~60% co-overexpressed HER2/*neu* and HER3, (3) HER1 was rarely co-overexpressed with HER2/HER3, and (4) HER4 was overexpressed in only 30% of the cases. c-Src was overexpressed in 70% of the samples. 90% of the tumor tissues overexpressed HER2, while 64% overexpressed c-Src. Growth in low serum was potentiated by HRG in five of six cell lines tested (irrespective of HER2/3 or c-Src levels), and colony formation in soft agar was enhanced in three of the six. This latter response was observed only in those cell lines that exhibited a c-Src/HER2 heterocomplex, suggesting that physical association between c-Src and HER2 may facilitate HRG-potentiated, anchorage-independent growth. HRG effects on both colony formation and growth in reduced serum were either partially or completely ablated by PP1, a Src family kinase inhibitor. In addition, long-term treatment of adherent cells with PP1 induced apoptosis in all cell lines tested, a process that was significantly reversed by HRG treatment. These data provide the first functional evidence for co-operativity between HRG and Src family kinases in the survival and growth of human breast

tumor cells and reveal that the co-operativity is independent of the levels of either HER family members or c-Src.

## INTRODUCTION

The HER family of transmembrane tyrosine kinases consists of four members, the human EGF receptor (EGFR or HER1), HER2/neu, HER3 and HER4. These receptors are involved in regulation of a number of different cellular processes, including mitogenesis, tumorigenesis, and differentiation (1, 2). HER1 has been shown to bind and become activated by different members of the EGF family of ligands, including EGF, TGF- $\alpha$ , epiregulin and betacellulin (3-8). HER4 binds betacellulin (5) and epiregulin (7), and like HER3, functions as a receptor for neuregulin 1 (also known as heregulin [HRG] and neu differentiation factor) and neuregulin 2 (9-11). However, no ligand has been identified for HER2. Rather, it has been demonstrated that HER2 is activated through heterodimerization with ligand-activated HER1, HER3 or HER4, with HER2/3 being the preferred and most tumorigenic heterodimer (12-15). Dimerization is followed by transphosphorylation between paired receptor monomers and stimulation or recruitment to the receptor complex of signaling molecules, including PI-3 kinase (phosphatidylinositol-3 kinase), Shc, GRB2, and GRB7 (16-19). In the HER2/3 heterodimer, HER3 (which exhibits reduced intrinsic catalytic activity [20]) appears to provide ligand binding activity and the ability to associate with PI-3 kinase, while HER2 contributes kinase activity and the ability to phosphorylate downstream substrates as well as the ability to associate with PI-3 kinase (9, 21, 22).

HER2 has potent oncogenic activity in cultured fibroblasts when overexpressed as a wild type protein, or when activated by a single point mutation in the transmembrane domain or by

deletion of the first 621 amino acids from the N-terminus (human [23]; rat [24]). Increased expression of HER2 is observed in a number of human cancers, including breast (25), ovarian (26), gastric (27), lung (28) and prostate (29). In breast cancers, overexpression and/or amplification of HER2, which occurs in ~ 30 percent of the cases, has been correlated with poor prognosis (25, 30). Overexpression of HER2 can function as a causal factor for breast cancer development, as has been demonstrated by targeted overexpression of HER2/*neu* and development of mammary tumors in mice (31).

Recently, several laboratories have reported the detection of elevated levels of c-Src protein/activity or physical complexes between members of the HER receptor tyrosine kinase family and c-Src in human and mouse mammary tumors (32-39). These findings suggest that a functional interaction occurs between these two families of tyrosine kinases in tumor formation and progression, but only in the case of HER1 and c-Src has such biological synergism been demonstrated. In a murine fibroblast model, overexpression of c-Src was found to potentiate tumorigenesis induced by overexpression of HER1. This potentiation correlated with the EGF-inducible formation of a stable complex between c-Src and HER1, the appearance of two novel tyrosine phosphorylation sites on the receptor, and enhanced phosphorylation of receptor substrates, suggesting that when both c-Src and HER1 are overexpressed (as in human breast cancer cells), c-Src functionally synergizes with the receptor by phosphorylating and activating it (36, 40, 41). The relevance of this model for human neoplasias is supported by an analysis of panels of human breast cancer cell lines and tumor tissues, in which overexpression of both c-Src and HER1 was found to correlate with the ability to detect a stable heterocomplex between c-Src and HER1, the appearance of the same two novel phosphorylations on the receptor, elevated tyrosine phosphorylation of downstream targets of HER1, and enhanced tumor formation in nude

mice (40). Together, these results indicate that structural and functional interactions between c-Src and HER1 play critical roles in breast cancer tumor progression.

To determine whether c-Src is capable of functionally interacting with other HER family members as it does with HER1, a panel of human breast tumor cell lines and tumor tissues was first examined for levels of HER family members and c-Src and for evidence of physical interactions between HER2 and c-Src. Using a subset of these lines (selected for various patterns of HER family member and c-Src overexpression and HER2/c-Src association), HRG was used as a ligand to activate HER2 through HER3 or HER4. We observed that HRG increased colony formation in soft agar two to three fold above that in serum alone and that this enhanced anchorage-independent growth correlated with the ability to detect stable c-Src/HER2 complexes. Anchorage-dependent growth in low serum was also enhanced by HRG, but to varying extents among the six cell lines tested. No correlation was observed between levels of c-Src or HER2/3/4 and the ability of HRG to enhance growth. However, in all cell lines, HRG-enhanced growth in reduced serum and soft agar colony formation were partially or completely inhibited by PP1, a Src family kinase inhibitor (42). Interestingly, extended PP1 treatment was found to induce apoptosis, and HRG rescued this effect. Taken together, these data provide evidence for co-operation between c-Src and HER2 in mediating HRG-induced growth and survival of human breast tumor cells.

## MATERIALS AND METHODS

**Cell lines.** Tumor cell lines MDA-MB-468, MDA-MB-231, MCF7 and ZR75-1 were provided by N. Rosen (Sloan-Kettering, New York), while MDA-MB-175, UACC-893, UACC-812, SK-BR-3, MDA-MB-361, MDA-MB-453, BT-474, BT-549, BT-20 and HS578Bst were obtained

from American Type Culture Collection (Rockville, MD). Tumor cells were maintained in Dulbecco's modified Eagle medium (DMEM) (Life Technologies, Bethesda, MD) in 10% fetal calf serum (Atlanta Biologicals, Atlanta, GA). Where indicated, cells were stimulated with recombinant human HRG- $\alpha$ , EGF-like domain (HRG- $\alpha$ ) (200ng/ml) (Sigma Chemical, St. Louis, MO) or HRG- $\beta$ 1 (extracellular domain) (NeoMarkers, CA). HRG- $\alpha$  and HRG- $\beta$ 1 gave nearly identical results and were used interchangeably.

**Growth assays.** Tumor cell lines were plated in triplicate in DMEM plus 0.5% fetal calf serum at a density of either  $2 \times 10^4$  cells/well (MDA-MB-468, MCF7) or  $5 \times 10^4$  cells/well (UACC-812, SK-BR-3, MDA-MB-361, MDA-MB-453) in 24-well tissue culture clusters (Corning, NY) and allowed to adhere overnight at  $37^\circ\text{C}$  in a humidified, 5%  $\text{CO}_2$  atmosphere before treatment protocols were initiated. Cells were then incubated for five days with one of the indicated preparations in DMEM. Media with additives was replenished on the third day. Cell number was determined by the MTT (3-(4,5-dimethyl-2-thiazolyl)-2,5-diphenyl-2H-tetrazolium bromide) assay as per Kaspers, *et al.* (43). The Src family kinase inhibitor, PP1 (42), was obtained from CalBiochem, San Diego, CA.

Soft agar assays were performed as described by Maa, *et al.* (36). Cells were plated at a density of  $1 \times 10^4$  cells in 60 mm dishes in triplicate, in the presence or absence of HRG- $\alpha$  (40ng/ml), and in the presence or absence of PP1 (10  $\mu\text{M}$ ). In the absence of PP1, DMSO was used as a vehicle control. Plates were incubated for two weeks, with replenishment of appropriate media every 4 days, and stained overnight at  $37^\circ\text{C}$ , 5%  $\text{CO}_2$  in a solution of 1  $\mu\text{g}/\text{ml}$  iodonitrotetrazolium salt (Sigma Chemical, St. Louis, MO) in water. Colonies were counted using EagleSight analysis software (Stratagene, La Jolla, CA).

**Antibodies.** C-Src-specific antibodies used in this study include mouse monoclonal antibodies (mAb) 2-17, directed against amino acids 2-17 (Quality Biotech, Camden, NJ); mAbs GD11 and EB8, both directed against residues 92-128 in the SH3 domain (44, 45); and mAb 327, which recognizes the SH3 domain (gift from J. Brugge). HER2-specific antibody (rabbit polyclonal), directed toward residues 1169-1186, and HER3-specific antibody, directed toward residues 1307-1323, were obtained from Santa Cruz Biotechnologies, Santa Cruz, CA, USA. Antibodies specific for HER1, mAbs 3A and 4A, were provided by D. McCarley and R. Schatzman of Syntex Research, Palo Alto, CA. The epitopes of these antibodies map to amino acid residues 889-944 and 1052 and 1134, respectively (36). Anti-human c-erbB-4 antibodies were obtained from Upstate Biotechnology, Inc. (UBI), Lake Placid, NY (catalog #06-572) and Santa Cruz Biotechnologies (catalog #SC-283). Negative control antibodies included purified normal rabbit or mouse immunoglobulin (Jackson Immunoresearch Laboratories, West Grove, PA, USA).

**Immunoprecipitation and Western immunoblotting.** Cells were lysed in RIPA detergent buffer (10mM Tris-HCl pH 7.2, 1% Triton-X, 0.5% sodium deoxycholate, 150mM NaCl, 1mM EDTA, 1mM sodium orthovanadate, 50 µg/ml leupeptin and 0.5% aprotinin). Tumor samples were minced with a scalpel and ground in a Dounce homogenizer in RIPA buffer. All procedures were performed at 4-10°C. Lysates were cleared by centrifugation for 15 min at 15,000 x g in a microcentrifuge, and protein concentration was determined by BioRad protein reagent. For immunoprecipitation, 5 µg antibody was incubated with 500 µg cell lysate protein with continuous rocking at 4°C for 2 hr and then for an additional hour at 4°C with protein A-sepharose beads (Sigma Chemical). Beads were pelleted and washed three times with cold RIPA buffer. Pellets were resuspended in 2X sample buffer (125mM Tris-HCl, 4% SDS, 10% glycerol, 0.02% bromophenol blue, 4% β-mercaptoethanol) and boiled for 5 min. Eluted proteins were

separated by electrophoresis through a 7% SDS-polyacrylamide gel and immunoblotted according to previously published protocols (36, 37). For direct Western blots, 100 µg whole-cell lysate was assayed per lane. Binding of primary antibodies was visualized by  $^{125}\text{I}$ -protein A, used at 1 µ Ci/ml (New England Nuclear, USA), or by enhanced chemiluminescence (ECL) (Amersham, Buckinghamshire, England).

For Western blots of HER4, proteins were transferred from gels to Immobilon membranes using the semi-dry apparatus. Membranes were blocked in phosphate-buffered saline (PBS) containing 4% non-fat dry milk and incubated overnight at 4°C with a mixture of the two primary anti-HER4 antibodies at a final concentration of 2 µg/ml. Membranes were washed five times in deionized water and incubated with  $^{125}\text{I}$ -goat anti-rabbit IgG in 4% non-fat dry milk in PBS for 90 min at room temperature. Five washes in water, a single wash in PBS, and five additional washes in water followed. The blot was exposed to film overnight at -70°C.

**Apoptosis Assays.** Apoptosis was quantified by determining the percentage of cells that exhibited deformed nuclei and/or condensed chromatin following DAPI (di-[amidinophenyl]-indole) staining of treated cells, as described by Villaneuva *et al.* (46). Briefly, cells were plated onto glass coverslips in 6-well dishes (Corning, NY), and incubated for three days with DMEM containing the indicated additives. UV-B treatment (2 min, followed by 48 hr recovery in serum-free media) was used as a positive control for apoptosis. After treatment, cells were serum-starved overnight, fixed in 4% paraformaldehyde, quenched in 0.25mg/ml H<sub>3</sub>BO<sub>4</sub> and 20mg/ml glycine, and permeabilized in 0.5% Triton-X on ice. DAPI (1.0 µg/ml) (Sigma Chemical, St. Louis, MO) was added for specific DNA staining, and nuclear/chromatin morphology was imaged by photomicroscopy using phase contrast and immunofluorescence optics (Leica, Rijswijk, Netherlands).

## **RESULTS**

**Overexpression of c-Src and HER family members in human breast carcinoma cell lines.** A panel of thirteen human breast carcinoma cell lines was analyzed by Western blotting for expression levels of c-Src and HER family members (a representative series of blots is shown in Fig. 1). Results of the scanning densitometry analysis of the immunoblots is shown in Table I. Nine of the cell lines (~70%) expressed c-Src greater than two-fold above the immortalized, non-tumorigenic human breast epithelial cell line, HS578Bst. All of the tumor cell lines overexpressed one or more of the four HER family members, in various combinations. Within any given cell line, however, overexpression of HER1 and HER2 appeared to be mutually exclusive. This finding agrees with published literature, which indicates that HER2 is typically expressed in earlier stage breast carcinomas (47-49), while HER1 is expressed in later, more aggressive tumors (50, 51). In addition, HER2 and HER3 were found to be co-overexpressed in the majority of cell lines (~60%), thereby enhancing the probability of formation of the preferred, more tumorigenic HER2/3 heterodimer. Under our immunoblotting conditions, only two cell lines, ZR75B and BT-474, were observed to have significantly elevated levels of HER4, with low levels being detected in SK-BR3 and MCF7. In summary, 100% of the breast tumor cell lines overexpressed one or more HER family member, while 70% overexpressed c-Src.

**Physical association of c-Src with HER2 in human breast carcinoma cell lines.** To determine whether there were potential structural and functional interactions between c-Src and HER2, such as exists between c-Src and HER1, we analyzed the panel of human breast carcinoma cell lines for evidence of *in vivo* association between c-Src and HER2. Figure 2, Panel A depicts results from an analysis of four of the thirteen cell lines tested (MDA-MB-361, MDA-MB-453, MCF7, MDA-

MB-468), and the outcome of the entire analysis is summarized in Table I. In only three cell lines of the entire panel could we detect a stable *in vivo* association between c-Src and HER2 (MDA-MB-361, MDA-MB-453, UACC-812), although nine overexpressed HER2 and five of the nine overexpressed c-Src. The presence of HER2 in c-Src immunoprecipitates was reproducibly seen, but detection of c-Src in HER-2 immunoprecipitates was variable. The reason for this is unclear, but could relate to the relatively low stoichiometry of the interaction. Association was constitutive in serum-deprived cells and was not altered by HRG stimulation (200ng/ml for 5 min) (Figure 2, Panel A). Only one of the three cell lines that showed association overexpressed c-Src (MDA-MB-361), indicating that association was not dependent on overexpression of c-Src. However, HER2 and HER3 were overexpressed in all three cell lines.

The low level of c-Src in the MDA-MB-453 and UACC-812 cell lines complicated our efforts to convincingly demonstrate that c-Src was indeed in the HER2/c-Src complex. However, despite the fact that c-Src could not be detected by Western blotting in whole-cell lysates (Fig. 1 and Table I) or in some c-Src-immunoprecipitations using 2-17 c-Src-specific mAb and 500 µg lysate (Fig. 2A with the MDA-MB-453 cell line), Figure 2, Panel B shows that c-Src could be detected in the MDA-MB-453 cell line when a mixture of Src antibodies to the N-terminus (2-17 mAb) and the SH3 domain (GD11) and 2500 µg lysate were used. Similar results were seen with the UACC-812 cell line. Thus, c-Src was detectable in the complexes precipitated from the MDA-MB-453 and UACC-812 cell lines, but in low amounts. A panel of c-Src-specific antibodies (directed to different regions of the c-Src molecule) and negative control antibodies was also used to determine specificity of the interaction. Figure 2, Panel C shows that co-immunoprecipitation of HER2 with c-Src was specific, as evidenced by the presence of HER2 in complexes with c-Src

and by the absence or significantly reduced levels of a similarly migrating protein in the negative antibody control precipitates.

**Association of c-Src with HER2 in human breast tumor samples.** Because HER family members and c-Src have been implicated in the formation of human breast tumors, we wished to determine whether c-Src/HER2 complexes existed in human breast carcinoma tissue or in normal breast tissue (as they did in established tumor cell lines), and if so, how frequently. A panel of thirteen tumor tissues, obtained from the University of Virginia and University of Michigan tumor banks, was analyzed by immunoprecipitation and Western blotting with antibodies to HER2 and c-Src, in a fashion similar to that used for the breast tumor cell lines. Figure 3 shows examples of this analysis. Tumors UVA156 and UVA263 exhibited c-Src/HER2 association, whereas MichN1 did not. In UVA263, reciprocal co-precipitation between c-Src and HER2 was observed. In addition, HER2/1 (UVA156 and UVA263) and HER2/3 (UVA156) complexes could be seen, indicating constitutive heterodimerization between HER family members in these tumors. Consistent with the data from the cell lines, this association was constitutive, suggesting the presence of an autocrine loop. Normal breast tissue contained detectable levels of c-Src but undetectable levels of HER2 and no association between HER2 and c-Src, HER1, or HER3. A protein of similar size as HER2 was sometimes seen to co-precipitate with the negative control antibody. The levels of this protein in control immunoprecipitates varied from experiment to experiment but were consistently less than that seen in the c-Src immunoprecipitates, and the protein exhibited slightly slower migration characteristics than did HER2 during gel electrophoresis.

Table II summarizes the results of such an analysis for all thirteen tumor samples and describes tumor type and grade, estrogen receptor (ER) status, lymph node involvement, relative

levels of c-Src and HER2 protein, and the presence or absence of a stable complex between c-Src and HER2 for each tumor. In all, stable association between c-Src and HER2 was seen in three out of thirteen samples, the same frequency as seen for the breast tumor cell lines. In contrast to the cell lines, however, c-Src/HER2 complexes were seen only in tissues that overexpressed both HER2 and c-Src. Complex formation between c-Src and HER2 has been demonstrated in mammary tumors in transgenic mice (33), but this is the first demonstration of an *in vivo* association in human breast carcinoma samples.

**HRG-enhanced soft agar colony formation is ablated by the Src family inhibitor, PP1.** In human breast tumor cell lines, HRG treatment has been demonstrated to increase tyrosine phosphorylation of many cellular proteins that are involved in mitogenic signaling pathways (52; Belsches-Jablonski, unpublished observations). It was therefore of interest to determine if HRG treatment affected the mitogenic or tumorigenic properties of these cell lines. To investigate this question, we chose a subset of the cell lines described in Table I, based on their varying expression of HER family members and c-Src. Three cell lines (MDA-MB-361, MDA-MB-453, and UACC-812) were selected because they co-overexpressed moderate to high levels of HER2 and HER3 and exhibited HER2/c-Src association. Of these, only MDA-MB-361 overexpressed c-Src. MCF-7, MDA-MB-468 and SK-BR3 cells were selected on the basis of their relatively low levels of HER2/HER3, moderate to high levels of c-Src, and lack of detectable HER2/c-Src complexes.

Figure 4 shows that only the cell lines that co-overexpressed HER2 and HER3 and contained c-Src/HER2 complexes (MDA-MB-361, MDA-MB-453, UACC-812) responded to HRG in a soft agar colony formation assay. HRG treatment potentiated anchorage-independent growth of these cell lines two to three-fold over that in 10% serum (Fig. 4, inset), while having no

significant effect on serum-induced colony formation of MCF7, MDA-MB-468, or SK-BR3 cell lines. Two of the latter three cell lines (MCF7 and MDA-MB-468) exhibited a robust colony forming activity that could not be augmented further by HRG, most likely since they are maximally activated by autocrine factors involving other signaling pathways (e.g., HER1/TGF $\alpha$  in the case of MDA-MB468 cells). SK-BR3 cells, in contrast, displayed poor growth in soft agar that was unaffected by HRG, suggesting that the signaling components to mediate HRG effects are either not present or are uncoupled in this cell line. As a whole, these data are consistent with the hypothesis that HRG-induced heterodimerization of HER2 and HER3 and the pre-existence of a c-Src/HER2 complex functioned together to promote a ligand-dependent enhancement of anchorage-independent growth, an indicator of tumorigenicity.

To test this hypothesis further, sister cultures of those depicted in the inset of Fig. 4 were treated with the Src family tyrosine kinase inhibitor, PP1, in the presence or absence of HRG and in the continual presence of 10% serum. Figure 4 shows that PP1 partially or completely inhibited HRG-enhanced soft agar growth in MDA-MB-361, MDA-MB-453, and UACC-812 cells, as well as variably reducing growth in serum plus HRG in MCF7, MDA-MB-468, and SK-BR3 cells. Furthermore, PP1 had a striking inhibitory effect on the ability of all cell lines to form colonies in serum alone, suggesting that PP1 is capable of affecting other growth pathways in addition to those that are HRG-induced. The results of this experiment could also be interpreted to mean that HRG “rescues” PP1-induced inhibition, again to variable extents in the various cell lines.

**HRG-potentiated anchorage-dependent growth is partially dependent on Src family kinases.** Because HRG treatment led to an increase in anchorage-independent growth of the three cell lines that co-overexpressed HER2 and HER3 and contained constitutive c-Src/HER2 complexes, we wished to determine whether HRG also affected anchorage-dependent growth of

these and other cell lines. An MTT assay was used to follow cell number as a function of incubation time in the various treatment conditions. No effect of HRG on the cell number of any of the cell lines was observed in 10% serum, even when assessed up to two weeks after plating (data not shown). However, Figure 5 shows that HRG treatment resulted in small, but significant increases in numbers of MDA-MB-361, UACC-812, and MCF7 cells, when they were maintained in reduced serum (0.5%) over a five day period (Panels A, B, C; compare "day 5" to "day 5+H"). Interestingly, the effect of HRG on cell number in this anchorage-dependent assay did not correlate with the presence of a c-Src/HER2 complex nor with levels of the various HER family members.

PP1 treatment prevented growth or reduced the cell number of all cell lines maintained in low serum alone (Fig. 5; compare "day 5 + P" to "day 5" in each panel), but the effect of PP1 on cells treated with HRG varied from cell line to cell line. HRG-treated MDA-MB-361 and MCF7 lines were only slightly reduced in cell number by PP1 treatment (Fig. 5, Panels A and C; compare "day 5 + H + P" to "day 5 + H"), whereas UACC-812 was reduced to levels equal to or below that of cells maintained in 0.5% serum alone (Panel B). These results suggest that c-Src and/or related family members cooperate with HRG to promote anchorage-dependent growth and/or survival of the breast cancer cell lines tested, but the extent of this cooperation varies from cell line to cell line. Results similar to those for MCF7 cells were found for MDA-MB-468 and SK-BR3 cells. MDA-MB-453 cells did not respond to HRG in this assay (data not shown).

PP1 has previously been shown to inhibit Src family members, Fyn and Lck (42). To determine whether PP1 also inhibited c-Src kinase activity, immune complexes of c-Src that had been prepared from MDA-MB-361 were preincubated for 15 min with varying concentrations of

PP1 (ranging from 0.1  $\mu$ M to 10  $\mu$ M) before the auto- and trans-phosphorylating activities were assessed in an *in vitro* immune complex kinase assay, using heat-denatured enolase as an exogenous substrate and/or [ $\gamma$ -<sup>32</sup>P]-ATP. Both the auto- and trans-phosphorylating activities of c-Src were reduced by PP1 in a dose- and time-dependent manner (data not shown). The IC<sub>50</sub> was 0.3 - 1.0  $\mu$ M PP1 in a 10 min incubation. These results verified that PP1 is an efficient inhibitor of c-Src kinase activity.

To further assess the role of c-Src and its family members on the growth and viability of breast cancer cells, we attempted to generate stable transfectants of MDA-MB-361 cells that expressed a dominant negative, kinase-deficient form of chicken c-Src (V430A) (53) that had been subcloned into the pcDNA3 mammalian expression vector (Invitrogen; 54). Transfected cells were selected for neomycin resistance, and early, antibiotic-resistant populations of cells were shown to express high levels of the variant form of c-Src by Western blotting with the chicken c-Src-specific mAb, EC10. However, no long-term stable clones could be obtained from this population, even after repeated efforts (data not shown). These data suggest a striking dependence on c-Src kinase activity for long-term survival and growth of these cells, even in full serum conditions. Not all human breast cancer cell lines behaved as did MDA-MB-361 cells, in that stable clones expressing kinase-defective c-Src could be obtained from them. Examples of such cell lines include MDA-MB-468 and MDA-MB-231. Similar to MDA-MB-361 cells, however, their tumorigenic properties were impaired (54).

**Heregulin reverses the apoptotic effect of PP1 in reduced serum.** Because the effect of HRG on anchorage-dependent growth in reduced serum was so modest and PP1 had such a deleterious effect on the growth and viability of the majority of cell lines tested (which was partially or completely reversed by HRG), we examined several of the cell lines (MDA-MB-361, UACC-812,

and MCF7) for possible evidence of an apoptotic effect of PP1 and an anti-apoptotic effect of HRG. Cells were cultured for three days in the presence or absence of HRG and/or PP1 and analyzed for evidence of apoptosis, using DAPI-staining of DNA to detect abnormally shaped nuclei and/or condensed chromatin (46). Figure 6, Panel A shows that PP1 treatment of MDA-MB-361 cells induced apoptosis in 10-15% of the cells (vs. ~2% in 0.5% serum alone) and that PP1-induced apoptosis was almost completely reversed by HRG. UV-induced apoptosis was used as a positive control (>85%). Similar results were obtained when UACC-812 and MCF7 cells were examined, except that the extents of reversal differed slightly (Fig. 6, Panels B and C). In all cell lines, the anti-apoptotic effects of HRG were found to be insensitive to Wortmannin, suggesting a PI-3 kinase-independent mechanism of action by HRG. Results of the DAPI analysis were verified with the TUNEL assay for apoptosis (data not shown).

## DISCUSSION

Both HER family members and c-Src are overexpressed at high frequency in human breast cancers (25, 30, 32, 37, 50, this report) and have been implicated in the genesis and progression of the disease. Amplification/overexpression of HER2, especially, has been associated with a poor patient prognosis (25, 30). Synergistic interactions between c-Src and HER1 in tumor formation have recently been reported (36, 37), and c-Src has been shown to be required for EGF-induced mitogenesis (53, 55), suggesting that similar interactions may exist between c-Src and other HER family members. Here we describe the results of experiments designed to investigate this issue in the context of human breast tumor cell lines and tumor tissue. In these studies, tumor cell lines were treated with ligands that activate HER3/4 and induce homo- and hetero-dimerization with HER2 as well as with an inhibitor of Src family kinases, PP1, to

determine if c-Src or related kinases contribute to HRG-initiated events. We found that HRG-enhanced colony formation in soft agar and adherence-dependent proliferation are inhibited by PP1, suggesting that Src family members participate in HRG-mediated growth processes in human tumor cells. However, we also found that the extent of the effects of PP1 (and thus presumably the effects of Src family kinases) are cell-line dependent, i.e., partial inhibition in some cell lines and complete inhibition in others (Figs. 4 and 5). Heregulin was also shown to reverse the growth inhibitory or apoptotic effects of PP1 (Figs. 4-6). Together, these results indicate that Src family kinases participate in HRG-regulated cellular processes and vice-versa, but the extent to which this occurs is likely to be determined by the unique signaling circuitry of each tumor cell line. These results are also suggestive of Src-independent as well as Src-dependent mechanisms for HRG action.

One mechanism by which HRG may be dependent on Src family members is through physical association of HER2 with c-Src. In such a scenario, c-Src might be thought to function by facilitating formation of heterocomplexes between HER2 and other HER family members or by phosphorylating HER2 or one of its receptor partners, as has been shown for HER1 (36, 40). These possibilities warrant further testing in a non-tumorigenic cell system, where the constituents of the complex can be regulated by overexpression and tumor-specific modifications to the receptor are eliminated.

In 23% of cell lines and tumor tissues tested (3/13 in each case), a stable and specific association between c-Src and HER2 was observed. In each of the cell lines exhibiting this association, HER3 is present and HER4 is undetectable (Fig. 1, Table I). These data argue that the functional complex mediating growth potentiation effects in soft agar assays is comprised of c-Src, HER2, and HER3 (12-15). The ability to detect c-Src/HER2 complexes correlated with the

ability of HRG to promote colony formation in soft agar, suggesting that the complex may participate in anchorage-independent growth. Involvement of c-Src in such a process is consistent with its documented roles in regulating focal adhesion formation (cell-substratum interactions) and inter-cellular interactions via cadherins (reviewed in 56, 57). Indeed, we have observed complete inhibition of p190RhoGAP, p130CAS, and cortactin tyrosine phosphorylation in five different human breast tumor cell lines treated with PP1 (D. Tice and S. Parsons, unpublished observations). These proteins are all demonstrated substrates of c-Src and involved in signaling pathways that regulate the actin cytoskeleton (reviewed in 58).

However, the ability to detect c-Src/HER2 complexes in the various breast tumor cell lines did not correlate with the anchorage-dependent growth-promoting or the anti-apoptotic effects of HRG (Table I, Figs. 5 and 6). Furthermore, in some cell lines and tissues where the complex was found, the stoichiometry of the interaction was low, raising questions about its physiological significance. These considerations suggest that Src family members may communicate with HER2 via other mechanisms. Alternative mechanisms include the following: The first presupposes that in some cell types HER2 and c-Src do not physically interact but are members of the same pathway and that HRG treatment indirectly induces changes in c-Src or its related family members which results in transmission of the growth or survival signal to downstream components. Given the result that HRG can reverse the apoptotic effect of PP1 (Fig. 6), HRG could be viewed as having the capability to override the inhibitory action of PP1 on c-Src or other family members. In this situation, HRG could function either upstream or downstream of c-Src, the latter through a feedback loop. In either case, we have found that the action of PP1 on Src family members is reversible both *in vivo* and *in vitro* (Belsches-Jablonski, Cox, and S. Parsons, unpublished), indicating that such a competitive action of HRG is possible.

Another potential mechanism of Src/HER2 interaction suggests that the two kinases are members of different pathways, which converge downstream of the points of action of c-Src and HER2. Since c-Src and its related family members are known to be involved in multiple growth factor-regulated responses (EGF, PDGF, G protein-coupled [53, 58-62]), such pathways could converge on HRG-stimulated pathways downstream of the action of Src. In favor of this possibility is our inability to detect c-Src activation in response to HRG treatment (data not shown), a finding that is consistent with the notion that c-Src does not lie directly downstream of HRG receptors.

Alternatively, HRG could be activating Src family members other than c-Src. Fyn and Yes have been found to be activated in certain types of human tumors, such as colon (63, 64) and lung (65, 66). However, these family members appear to be less frequently activated or overexpressed in human breast cancer cells or tissues than is c-Src (37; reviewed in 67), suggesting that c-Src is an appropriate focus of our attention for these studies.

Despite the structural similarities between HER1 and HER2 and their involvement in the genesis of breast cancer and other human tumors, there are striking differences between c-Src/HER1 and c-Src/HER2 complexes. In both a murine fibroblast model system and in a subset of human breast tumor cell lines, physical association of c-Src with HER1 is EGF-dependent, and was found to occur only in the presence of overexpression of both c-Src and HER1 (36, 37). In contrast, in human tumor cell lines, the formation of HER2/c-Src complexes is constitutive, not dependent upon overexpression of c-Src, and insensitive to HRG treatment. Given the many ligands that have been shown to bind to HER family members, it is reasonable to speculate that autocrine production of ligands could cause constitutive activation of the receptors and thus association with c-Src. In support of this is our finding that p-Tyr-containing proteins in the 170-

185 kDa range are seen in p-Tyr immunoblots of unstimulated lysates from each cell line which contains the c-Src/HER2 complex (data not shown). Treatment of these cell lines with EGF or HRG did not increase the overall amount of p-Tyr signal, consistent with the notion that the endogenous receptors were already activated.

The correlation between the ability to detect a c-Src/HER2 complex in certain cell lines and to observe a biological effect on HRG-induced growth in soft agar suggests that this complex may be important in promoting malignant transformation. The functional linkage between Src family kinases and HRG in both the anchorage-independent and -dependent growth assays provides additional support for the hypothesis that c-Src and HER2 co-operate at many levels to increase tumorigenicity, as we and others have demonstrated for c-Src and HER1 (36, 37, 40, 41, 58, 67). However, from available evidence we believe that the mechanism of co-operativity between c-Src and HER2 will be revealed to be different from that of c-Src and HER1. For example, we have not observed a common downstream signaling molecule that is activated in the various breast tumor cell lines by HRG, while Shc and MAP kinase have been routinely found to be activated in many of those same cell lines by EGF (37; Belsches-Jablonski and S. Parsons, unpublished). Current efforts are directed toward understanding the nature of the physical interaction between c-Src and HER2 (direct or indirect) and the signaling pathways that convey their overlapping and unique directives to the nucleus.

#### **ACKNOWLEDGMENTS**

The authors thank Dr. S. Ethier of the University of Michigan and A. Ingram from the University of Virginia Tissue Procurement Facility for tumor tissue, and members of the T. Parsons, M. Weber, and S. Parsons laboratories for their critical evaluation of this work. These studies were supported by grants CA71449 of the NIH and 4621 of the Council for Tobacco Research,

awarded to SJP. APB-J and JSB are recipients of post-doctoral fellowships (DAMD 17-96-6098 and DAMD 17-97-7329, respectively), and DAT is a recipient of a pre-doctoral fellowship (DAMD 17-96-6126), all from the Army Breast Cancer Initiative, D.O.D.

## FIGURE LEGENDS

**Figure 1. Overexpression of HER family members and c-Src in human breast carcinoma cell lines.** Lysates from indicated cell lines were prepared in RIPA buffer, and 100  $\mu$ g protein was loaded per well in a 7% polyacrylamide gel. Western blots were probed with antibodies to c-Src (2-17); HER1 (3A and 4A); HER2 (Santa Cruz SC-284); HER3 (Santa Cruz SC-285); and HER4 (Santa Cruz SC-283/UBI #06-572). Primary antibodies were visualized by  $^{125}$ I-protein A, except for the HER4 antibodies, which were detected with  $^{125}$ I-goat anti-rabbit IgG. Portions of this figure are reproduced from ref. 37, Copyright 1998, Wiley-Liss, Inc., a subsidiary of John Wiley & Sons, Inc.

**Figure 2. Physical association between c-Src and HER2 in human breast carcinoma cell lines.** **Panel A:** MDA-MB-361, MDA-MB-453, MCF7 and MDA-MB-468 cells were serum-starved for 17 hr. and either stimulated with 200 ng/ml HRG- $\alpha$  (+) or incubated in fresh serum-free media (-) for 5 min. Cells were then lysed, and 500  $\mu$ g lysate protein from each cell line and treatment protocol was incubated with either anti-Src (S) (2-17 mAb), anti-HER2 (H2) or mouse IgG. Precipitated proteins were separated by SDS-PAGE and transferred to a nylon membrane. The upper half of the membrane was probed with anti-HER2 primary antibody, and the lower half was probed with anti-Src (2-17) primary antibody. Both primary antibodies were visualized by  $^{125}$ I-protein A. **Panel B.** MDA-MB-361 and MDA-MB-453 cells were treated as in (A), except that 2.5 mg lysate protein and a mixture of 2-17 and GD11 c-Src-specific mAbs were used for the immunoprecipitation. The nylon membrane was probed with 2-17 mAb. Primary antibody was visualized by  $^{125}$ I-protein A. **Panel C.** Lysates from unstimulated MDA-MB-361 cells were prepared as in (A), and 1.0 mg lysate protein was immunoprecipitated with each of four different antibodies to c-Src (see Materials and Methods), as well as mouse anti-rabbit (MAR) or mouse IgG as negative antibody controls. Immunoblots were prepared as in (A).

**Figure 3. Presence of endogenous c-Src/HER2 complexes in human breast tumor tissue.** Tumor lysates were homogenized, lysed in RIPA detergent buffer, and clarified by centrifugation. Cellular proteins were immunoprecipitated with anti-Src (S), anti-HER1 (H1), anti-HER2 (H2), or anti-HER3 (H3) antibodies from 250  $\mu$ g lysate protein. Precipitated proteins were separated on 7% polyacrylamide gels and transferred to nylon membranes. The upper half was probed with

anti-HER2, and the lower half with 2-17 mAb. Both primary antibodies were visualized by  $^{125}\text{I}$ -protein A. (-) indicates mouse anti-rabbit IgG as a negative control for immunoprecipitation.

**Figure 4. Effects of HRG and the Src kinase family inhibitor, PP1, on anchorage-independent growth of human breast tumor cells.** MDA-MB-361, MDA-MB-453, UACC-812, MCF7, MDA-MB-468 and SK-BR3 cells were plated in soft agar as described in Materials and Methods and incubated at 37°C in a humidified, 5% CO<sub>2</sub> atmosphere for two weeks in DMEM containing the following: 10% serum + DMSO vehicle control; 10% serum + 40 ng/ml HRG- $\alpha$  + DMSO vehicle control; 10% serum + 40 ng/ml HRG- $\alpha$  + 10  $\mu\text{M}$  PP1; or 10% serum + 10  $\mu\text{M}$  PP1. Media with additives was replenished every 4 days. Colonies were stained, counted, and expressed as the mean colony number  $\pm$  SEM of three independent experiments, each performed in triplicate. Inset depicts fold difference of HRG treatment over non-stimulated controls. \* = significantly different than 10% serum alone (p-values  $\leq 0.05$ ).

**Figure 5. Effects of HRG and PP1 on anchorage-dependent, reduced-serum growth and survival of human breast cancer cells.** MDA-MB-361 (**Panel A**), UACC-812 (**Panel B**), and MCF7 (**Panel C**) cells were plated in DMEM with the following additives: 0.5% serum + DMSO vehicle control; 0.5% serum + 40 ng/ml HRG- $\alpha$  or - $\beta$  + DMSO vehicle control; 0.5% serum + 40 ng/ml HRG + 10  $\mu\text{M}$  PP1; or 0.5% serum + 10  $\mu\text{M}$  PP1, as described in Materials and Methods. The cultures were incubated for 5 days, with replenishment of media containing the appropriate additives at day 2.5. Cell number at Days 0 and 5 was determined by the MTT assay and is expressed as mean fold-change  $\pm$  SEM relative to Day 0. Day 0 density was determined 12 hr after plating. Results are pooled from 4 independent experiments, each performed in triplicate. #

= significantly different than day 5, 0.5% serum alone.  $\psi$  = significantly different than day 5, 0.5% serum + HRG. p-values  $\leq 0.05$ .

**Figure 6. Anti-apoptotic effects of HRG and Src family kinases in human breast tumor cell lines.** Cells were plated onto glass coverslips ( $5 \times 10^4$  cells/coverslip) and grown in one of the following, DMEM plus: 0.5% serum alone + DMSO vehicle control; 0.5% serum + 40 ng/ml HRG- $\alpha$  + DMSO vehicle control; 0.5% serum + 10  $\mu$ M PP1; or 0.5% serum + 40 ng/ml HRG- $\alpha$  + 10  $\mu$ M PP1, and incubated for 3 days. Cells were then fixed in 4% paraformaldehyde and permeabilized, and nuclei were stained for DNA with DAPI. At least 400 cells per treatment were counted for apoptotic nuclei in two separate experiments. A 2-min UV-B treatment and 48 hr recovery in serum-free media was used as a positive control for apoptosis. **Panel A:** MDA-MB-361; **Panel B:** UACC-812; **Panel C:** MCF7. \* = significant difference between 0.5% serum or 0.5% serum + HRG + PP1 and 0.5% serum + PP1 (p-values  $\leq 0.05$ ).

Table I<sup>†</sup>

# Human Breast Carcinoma Cell Lines

## Relative levels of HER family members and c-Src

cell line	<u>HER1</u>	<u>HER2</u>	<u>HER3</u>	<u>HER4</u>	Association of c-Src with:		
					c-Src	<u>ER</u>	<u>HER1</u>
MDA-MB175	*	2.2	6.1	*	9.9	+	-
UACC-893	*	72.8	6.7	*	*	-	-
UACC-812	*	50.8	6.1	*	*	-	ND
SK-BR-3	12.6	2.5	*	1.0	19.4	-	+
MDA-MB361	*	12.8	10.9	*	37.4	+	-
MDA-MB453	*	1.5	6.1	*	*	-	+
MDA-MB468	39.5	*	*	*	4.9	-	+

MDA-MB231	7.6	1.1	1.0	*	2.9	-	+
BT-20	3.4	1.9	5	*	13.5	-	+
MCF-7	1	1	2.3	1.5	6.4	+	-
Hs578Bst <sup>1</sup>	1	*	*	*	1	+	-

(\*) = below limits of detection

ND in table indicates no data.

<sup>†</sup>Autoradiographs from Figure 1 were analyzed by densitometry and compared to Hs578Bst<sup>1</sup>, an immortalized normal human mammary epithelial cell line. The lowest detectable signal on each blot was set as 1.0, and fold difference of the cell lines was determined. An \* indicates a signal was below the limits of detection by Western blotting. Also included in the table are estrogen receptor (ER) status of the cell lines, as determined by Western blotting (37), and physical association between c-Src and either HER1 or HER2, as determined by immunoprecipitation with monoclonal antibodies to c-Src. Portions of this table are re-printed from ref. 37, Copyright 1998, Wiley-Liss, Inc., a subsidiary of John Wiley & Sons, Inc..

Table II<sup>†</sup>

Summary of Human Breast Tumors Tested for Physical Association of HER2 and c-Src

Tumor	<u>Tumor Type</u>	<u>ER</u>	<u>Lymph Node</u>	<u>Src/HER2 Association</u>	<u>RELATIVE LEVELS</u>
UVA103	IVDC <sup>1</sup> , grade 3/3	-	-	-	ND <sup>6</sup>
UVA156	IDC <sup>2</sup> , grade 2/3	-	+	+	+++
